CASE 25.—A woman, aged forty-two years, was seen eighteen months after the attack. Her husband stated that she suffered from headache for three months, when loss of speech and hearing supervened, and symptoms of apparent dementia. She uttered inarticulate sounds almost all day long. She was after a time admitted to an asylum, where she remained for six months, to the date of her death. Whilst there she continued to mumble constantly, the only articulate sounds she uttered being "Tschen" and "Tscho." She occasionally moved her head when spoken to as if she heard, though she did not understand what was said. There was no paralysis or other motor disturbance. At the necropsy there was congestion of the membranes, the frontal and parietal convolutions were somewhat wasted, the sulci being wide and filled with serum. Over the left temporal lobe the pia was jelly-like, whilst its convolutions were swollen, pressed together, and of soft, jelly-like consistence. The right temporal lobe was also slightly softened. Sections showed that the softening was confined to the cortex—on the right side of all the temporal convolutions except the basilar, and on the left side to the same region. The foot of the third frontal convolution was not involved.

The second case is one that has been recorded by C. K. Mills,[12] and although the details of the necropsy are full and all that could be desired, the patient only came under his observation a few days before her death when she was very weak and ill, suffering from the effects of an old valvular disease of the heart. He says: "Some of the facts of her history were obtained from relatives who came to see her at the hospital, and others were procured after her death from a brother and sister-in-law, whom I sought out and carefully interviewed." The following are

all the particulars given that are of any importance from our point of view.

CASE 26.—A woman, aged forty-six years, was admitted to the Philadelphia Hospital in August, 1891. Fifteen years before her death she had an apoplectic attack which left her word-deaf but not paralysed. Prior to the first attack of apoplexy her hearing had been good, but after it she could not by hearing understand anything that was said to her. She could, however, hear music and sounds of various kinds; for instance, when an organ or band had performed in the street she at times had called attention to the fact, and she had also come down from the second or even the third storey to open the front door in answer to a knock. She could hear such sounds as a bell ringing and a clock ticking. These facts were elicited from her relatives through various statements made by them, chiefly spontaneously. When anyone wished to communicate with her it was done by means of writing or signs, as she had fully preserved her vision and was evidently not word-blind either for writing or printing. She often read the newspapers, and could do so with intelligence up to a few weeks before her death. [It correct this is remarkable, as it would have been long after the destruction of both auditory word-centres.] Her sister-in-law said that several times she had heard her try to read the newspaper aloud, and in so doing she had seemed to understand what she read, "but made a tangle of her words." From the time of the first attack she had never been able to speak well, her words becoming jumbled or tangled. From the description given of her manner of speech the defect was evidently a serious form of paraphasia and paralexia. Her relatives spoke positively of her deafness as having been due to the "stroke"; but the apoplectic attack, although it had at once caused this word-deafness and paraphasia, had not in any way, as far as could be ascertained, affected either motion or sensation. She could write, but "sometimes mixed up her words in writing." Nine years before her death she had another and more severe apoplexy, after which her deafness increased for sounds as well as words until it was almost total. This seizure left her also with partial left hemiplegia, chiefly affecting the arm. Dr. Mills adds: "She was first examined by me on Aug. 24th, 1891. Her condition then was one of almost complete helplessness. It was impossible to make her understand what was said to her, and, so far as could be determined by repeated tests, she was totally deaf; but notwithstanding her weakness, helplessness, and deafness, her face had a somewhat intelligent expression. She looked about her as if she knew what was going on. She was very emaciated; her heart's action was excited, and examination showed the presence of marked murmurs, both mitral and aortic She became feebler day by day, and died Aug. 28th." At the necropsy the posterior two-thirds of the left first temporal convolution was found to be shrunken to a thin strip, and the posterior fourth of the second temporal convolution was also atrophied. The other left temporal convolutions were healthy. On the right side there was an old and very extensive hæmorrhagic cyst, which had completely destroyed the first and almost completely the second temporal convolution, as well as the island of Reil and other parts in the immediate neighbourhood. (Very full details of the condition of the brain are given, and in the *Philadelphia University Medical Magazine* there are two excellent photogravures showing the extent of the lesions.)

This is undoubtedly a very important case, especially from the point of view of cerebral localisation, from which standpoint Mills principally deals with it. It is interesting to find that after the patient became word-deaf, owing to the first lesion on the left side, there was no word-blindness, as "she often read the newspapers and could do so with intelligence"—although some would have us believe that even the destruction of Broca's centre, which is so much further away from the visual centre, causes alexia. There was, however, paraphasia and paralexia. Unfortunately there is no definite statement as to what alteration took place in the patient's speech after the lesion occurred on the right side—that is, nine years before her death. I therefore wrote to Dr. Mills to ascertain whether he could supply any further information on this important point, and his reply is as follows: "She was admitted to the hospital some little time (probably two or three weeks) before I examined her, and my recollection is that it was reported to me that she had not spoken during that time, but more than this I cannot say ..... and unfortunately I have no longer the means of verifying my recollection. She certainly was not able to speak, or at least did not speak, at the time of my examination." I will merely add that, from the fact of the word-deafness in this patient not being associated with word-blindness, it does not necessarily follow that the paraphasic speech should have been lost—that is to say, that there should have been speechlessness—immediately after the occurrence of the lesion in the right hemisphere. There is the possibility that she might have been one of those "visuals" capable of speaking, though in a disordered fashion, by the direct action of the visual word-centre upon Broca's convolution. It seems pretty clear, however, from what Dr. Mills says, that at the time she went into the hospital she was incapable of speaking. Still, it is important to bear the above-mentioned possibility in mind, as it is one to which we shall have to recur.

The third case is one that was recorded by Wernicke and Friedländer[13] and an abstract of it has been given by Ferrier[14] which I will now quote.

CASE 27.—A woman, aged forty-three years, who had never suffered from deafness or affection of vision, was attacked on June 22nd, 1880, with right hemiplegia and aphasia. She remained in the hospital until Aug. 4th, when she was discharged. At this time the patient could speak, but she spoke unintelligibly, and was sometimes believed to be intoxicated. She not only could not make herself understood, but she could not understand what was said to her. She was received into the hospital again on Sept. 10th, with slight paresis of the left arm. The right hemiplegia had entirely disappeared. The patient was looked upon as insane She was absolutely deaf, so that she could not be communicated with. She died from an attack of hæmatemesis on Oct. 21st. An extensive lesion was found in each temporal lobe (of which figures are given). On the left side it involved the posterior half of the first and second temporal convolutions and a small part of the third; on the right side it involved the angular gyrus, the posterior extremity of the upper temporal convolution, and encroached slightly on the occipital convolutions.

The fourth case has been described by Pick. It is one of great importance, but as it is also one of a very exceptional nature I reserve its consideration for the present.

(3) DEFECTS RESULTING FROM DESTRUCTION OF THE AUDITORY AND VISUAL WORD-CENTRES IN EACH HEMISPHERE.

There is only one case known to me in which these combined lesions have existed in the two hemispheres, although there is another with which it will be not uninteresting to compare it where complete blindness and deafness had been produced in infancy by peripheral lesions.

The case definitely belonging to this category was reported many years ago by J. C. Shaw,[15] but unfortunately in this as in other rare cases many essential details are omitted. Still this case is so valuable by reason of its extreme rarity that we are glad to accept it notwithstanding the paucity of clinical details. All the essential recorded facts are these.

CASE 28.—A woman, aged thirty-four years, was admitted into King's County Lunatic Asylum on Sept. 25th, 1879. A few facts concerning her were obtained from a sister. Two months before admission she complained of being unable to use the right arm. Soon afterwards she had a sudden attack characterised by loss of consciousness, inability to speak, and loss of hearing. They did not notice at this time that she had any loss of vision. She is said to have remained "unconscious" about two weeks, after which she was able to get up, and then began to talk. But she could talk sensibly only for a few minutes, then she would ramble and become incoherent. The friends were indefinite as to the extent of her sight trouble at this time, but there seems to have been marked mental disturbance. The certificates committing her relate that "she says some men are trying to kill her; she screams without cause; and she is at times violent." The following meagre notes concerning her condition are then given:—"On admission she is found to be very stupid; does not answer any questions, evidently does not hear them; is quite deaf. Pupils slightly dilated and equal; she is evidently quite blind. Physical condition poor; habits dirty. Oct. 18th and Nov. 21st: Had a severe epileptiform fit on each of these days. Dec. 11th: Repeated tests of tactile sensibility and smell show them to be unimpaired, but she is absolutely deaf to all noises and also blind. Dec. 16th: Walks about the hall using disconnected and unintelligible words; at times speaking very loudly and screaming. Jan. 31st, 1880: Severe convulsions lasting seven hours. Muscular spasm most marked on left side (the right arm remained contracted afterwards during two days). Feb. 14th: Is up again; walks about; shows no sign of paresis anywhere. October: She has become quite noisy, talking and screaming unintelligibly night and day; is growing thinner and more stupid, if that were possible." The patient remained in about the same condition till September, 1881, when she developed a low form of pneumonia and died on Sept. 19th. At the necropsy an almost exactly symmetrical patch of cortical atrophy was found in each hemisphere. It involved (as is shown by two figures) the greater part of the upper temporal and angular gyri, the marginal lobule, and the upper parietal lobule on each side. In the affected areas it was found "that the grey matter had entirely disappeared, leaving the very outer layer to which the pia was attached and the white matter below, so that there was really a cavity or space between the two, formed at the expense of the grey matter. Microscopic examination showed this outer layer to be composed of dense connective tissue filled with nuclei." There was no atheroma of the great vessels, and, except that the patches of cortical atrophy mentioned involved on the left side a small portion of the upper part of the ascending parietal, and on the right side a small portion of the lower part of the corresponding convolution, other portions of the brain seem to have shown no appreciable lesion.

It is interesting to find also that in the celebrated case of Laura Bridgman, who was totally deaf and blind from about the end of her second year, her power of uttering articulate sounds was not very different in kind, though less in degree, than that which was met with in the case above recorded. The following account of her condition in this respect is given by Kussmaul[16]:—

CASE 29.—The child lost her eyesight and hearing about the end of her second year, when she was beginning to talk, and in consequence soon lost the power of speech. Now, although it may be assumed that she retained no memory of sounds, which long experience teaches us is the rule with those who become deaf-mutes so early, yet she was able to produce a multitude of sounds. She took the greatest pleasure in

giving utterance to these, and even went so far occasionally, in order to indulge herself in noises to her heart's content, as to lock herself up when her teachers endeavoured to restrain her from so doing. These noises were, in fact, inarticulate—e.g., a kind of chuckling or grunting, an expression of contentment; while others—e.g., "h-o-ph-ph"—were better formed, and served for an indication of astonishment. Other sounds, again, she elevated to the dignity of names, and bestowed them on certain persons. She uttered these latter when those so denominated approached her, or when she wanted to find them, or even at times when she only thought of them. She employed some fifty or sixty such sounds as names, many of which could be written down, such as fu, tu, pa, fifpig, ts, pr, lutt, &c.; many, however, it would be almost impossible to express in letters. She formed, however, only words of one syllable, but frequently re-duplicated them two or three times, as fu-fu-fu, tu-tu-tu.

There was therefore slowly developed in this child something more of method in the use of the simple or complex sounds that were uttered than has been met with in the early stages, or for some time after the onset, of the cases of disease in which both auditory word-centres have been destroyed. The sounds emitted were also less voluble and free, which is only to have been expected, seeing that in Laura Bridgman the glosso-kinæsthetic centres had never been developed as they have been in the case of patients who, by reason of the lesions above mentioned occurring in adult life, have been reduced to a condition in which their speech has become unintelligible. The powerlessness of Broca's centre when unaided for the production of anything like intelligible speech is, however, clearly shown.

After the narration of these additional cases in which there was a destruction of the auditory word-centre in each hemisphere we may now with more advantage return to the question why in a certain number of the cases of destruction of the left auditory word-centre alone there is (1) an aphasic loss of speech, in others (2) paraphasia, and in still others (3) a comparatively slight impairment in voluntary speech.

My original contention was that an aphasic loss of speech is what is naturally to be expected as a result of such a lesion, if we are to suppose, as seems highly probable, that the auditory word-centre in the great majority of persons holds a relation to Broca's centre similar to that which the visual word-centre holds to the writing centre. It would appear, therefore, that what stands in need of explanation is the occurrence of the second and third class of cases—namely, those in which more or less marked paraphasia, or even fair speech, has existed.

The evidence in favour of the posterior half of the upper, with perhaps the posterior part of the middle, temporal convolutions being the chief, if not the exclusive, seat of the auditory word-centre must be regarded as very conclusive.[17] The difference in voluntary speech power presented by the cases above referred to cannot therefore be explained by the supposition that the auditory word-centre has not yet been properly localised.

The various possibilities that suggest themselves to me in explanation of the differences in the degree of impairment of speech in different cases in which lesions have been found in the left auditory word-centre are as follows:—

(*a*) There is the possibility that in some of the cases in which the word deafness has been complete whilst voluntary speech has been fairly good the auditory word-centre has been rather isolated from its afferent fibres than destroyed. These would be cases in which the amount of damage to the auditory word-centre itself was small—cases approaching those named by Lichtheim "isolated speech-deafness," which will be subsequently considered.

(*b*) Then in some cases the auditory word-centre may be damaged sufficiently to prevent perfect comprehension of speech, though it may still be sound enough with the aid of the visual word-centre for the production of paraphasic speech. This might afford an explanation of certain cases in which there is only partial damage of the auditory word-centre, together with incomplete word-deafness, as in No. 7 in Amidon's list, and Nos. 2 and 48 of Mirallié's list, as well as in a case by West,[18] which is not included in either of them.

(*c*) In other cases, where the individuals affected are strong "visuals," the paraphasic speech may be produced by the action of the visual word-centre taking the place of the auditory word-centre—that is, by the passage of the stimulus directly from the visual word-centre to Broca's region across the commissure *e e*, as represented in Fig. 5. Such an explanation may be applicable to some of the cases where the destruction of the auditory word-centre has not produced word-blindness as well as word-deafness. And this, as we have seen, has been what has occurred in about two-thirds of the recorded cases.[19]

There is one extraordinary case that has been recorded by Pick[20] which seems, moreover, quite incapable of being understood except by the supposition of the adequacy of the direct action of the visual word-centre upon Broca's region even for the production of correct speech—as it is brought about, in fact, in all deaf-mutes who are taught to speak. This is the case of lesion in the upper temporal convolutions of each hemisphere, the consideration of which was deferred because of its altogether exceptional character. Although this patient was perfectly word-deaf, he was able to speak correctly, to read correctly, and to comprehend writing perfectly, as may be gathered from the following details.

CASE 30.—A day labourer, aged twenty-four years, was completely word-deaf and behaved like a deaf person, taking no notice of ordinary sounds near him. It was found that he only noticed loud calls, clapping, or ringing of bells, and this not always readily. Yet if one shouted to him unexpectedly, he said, angrily, "Don't shout at me so"; and he often said spontaneously, "I hear quite well but I don't understand; I can hear a fly flying past me." His power of recognising airs previously known to him seemed to be also lost. His speech was perfectly correct. He spoke fluently, and only occasionally hesitated about the right word. He named objects shown to him correctly. He could not repeat words or phrases. Writing was executed slowly but quite correctly, though he could not write from dictation. With regard to his power of copying nothing could be stated, as he could not be persuaded to make the attempt. He read aloud easily and quite correctly, and he understood both print and writing perfectly. Writing afforded the only means of communicating with him apart from gestures. The patient's condition in the above mentioned respects remained essentially unchanged during the whole period of his stay in the hospital, from Jan. 17th to May 12th, 1891. At the necropsy the upper parts of both temporal lobes were found to be shrunken, soft, and of a yellow colour. On the left side the posterior half of the upper temporal convolution and the supra-marginal gyrus were the parts that were softened. The island of Reil was intact. On the right side there was softening of the upper temporal convolution and a great part of the second temporal, as well as of the island of Reil, together with some small foci in the lower part of the ascending frontal, and in the third frontal, convolution.

It appears from the history of this patient that the first lesion occurred on the right side of the brain about ten years before his admission to the hospital. Six years later the lesion in the left hemisphere occurred, which resulted in the production of word-deafness. Speaking of this patient's condition during the four months that he was under observation Pick says that his intelligence was distinctly weakened and his behaviour childish. It was difficult to fix his attention; he was very emotional and spent much time in prayer. When so engaged no sort of noise seemed to disturb him, for, notwithstanding what he said as to his hearing, it appears that, like Lichtheim's patient,[21] he was also really very deaf to ordinary sounds. As above stated, there seems no way of explaining this case except by supposing that the left visual word-centre was capable of acting directly upon Broca's centre, and without any aid from the left auditory word-centre (the destruction of which had caused the word-deafness four years previously) of acting so effectively that the patient was capable of reading aloud and of speaking, even without making mistakes in words. The word-deafness was clearly caused by the lesion in the left auditory word-centre itself, and it seems equally certain, therefore, that this centre could not have been instrumental in enabling the patient to speak. It is superfluous, consequently, to look for a sub-cortical lesion.[22]

(*d*) Another possibility in explanation of the preservation of slight or disordered speech after destruction of the left auditory word-centre is that the auditory word-centre of the right hemisphere acts, by means of commissural fibres passing obliquely through the corpus callosum, upon the left third frontal convolution. This is a possibility which has not, I believe, been previously suggested by any writer on speech defects, though it seems to me almost the only means of accounting for the existence of speech of a paraphasic type in those cases where the destruction of the left auditory word-centre leads to word-blindness as well as to word-deafness—that is, in about one-third of the total number of such cases. The addition of word-blindness as a symptom in these cases must, as I have said, be supposed to

[17] On this subject see Ferrier on Cerebral Localisation, 1890, and C. K. Mills, in Brain, 1891.

[18] Brit. Med. Jour., vol. i., 1885, p. 1242.

[19] The next explanation is, however, equally applicable to this class of cases as well as to those in which word-blindness co-exists with the word-deafness.

[20] Archiv für Psychologie, 1892, p. 909.

[21] Loc. cit., p. 460

[22] Yet Mirallié actually quotes it as an example of a sub-cortical lesion

Hosted by Google

be due to the very close functional and topographical relations of the auditory and the visual word-centres; but if the visual word-centre has had its functional activity so deranged as to have led to word-blindness it cannot reasonably be supposed that it could in that state take on independent functions in the way of supplementing the activity of the destroyed auditory word-centre.

The argument in favour of the possible action of the right auditory word-centre in the manner indicated is, however, even stronger than that just stated, because we shall find in a future section, when dealing with cases in which there has been more or less complete destruction of both the auditory and the visual word-centres of the left hemisphere, that out of fifteen of such cases, in two speech is reported to have been fairly good, in seven there was jargon speech or paraphasia, whilst in six it was more or less markedly aphasic. But when the auditory and the visual word-centres of the left hemisphere are destroyed speech, if it is to be produced by that hemisphere alone, would have to be effected solely by Broca's centre. We have, however, already seen that with double destruction of the auditory word-centre, as well as with double destruction of the auditory and the visual word-centres, speech has always been rendered unintelligible, except in one single case—that of Pick, above recorded. It thus seems to stand out very clearly that Broca's centre alone is not capable of acting as an instigator and adequate guide for the production of intelligible speech. We have good reason for believing, moreover, as I have previously pointed out, that it is not a centre whose images are much used as counters for thought, although the rousing of the sub-conscious memories of this centre is, under proper guidance, essential for the production of speech as a series of voluntary movements.

We are therefore absolutely driven to look for aid or guidance from the right hemisphere if we are to account for the production of even paraphasic speech in cases of damage to the left hemisphere of such a nature that word-deafness is associated with word-blindness, whether the latter be of structural or of functional origin. This same hypothesis enables us to understand the unintelligible character of the speech in three out of the four cases cited of double destruction of the auditory word-centre, as well as in the case in which the auditory and the visual word-centres were destroyed in each hemisphere. The old notion that intelligible speech can be initiated and produced by the influence of Broca's centre alone must be absolutely renounced.

By reference to other considerations it may also be shown to be by no means devoid of probability that both auditory word-centres are actually in structural relation with, and therefore capable of acting upon, the glosso-kinæsthetic centre of the left hemisphere. It will not be difficult to show that the notions hitherto prevalent in regard to the understanding of spoken and written language and the utterance of speech have probably left altogether too much out of account that conjoint activity of the right and left hemispheres which almost certainly exists in connexion with perceptive processes, and which therefore we may suppose exists in connexion with derivative intellectual processes, as well as during the initiation of all sorts of motor reactions directly or indirectly following thereupon.

It is well known that each olfactory bulb and that each retina is connected with both cerebral hemispheres. Modern knowledge compels us to believe that in every act of visual perception the half-vision centres in each occipital lobe are called into concurrent activity. It would be contrary to existing knowledge for us to suppose that the cochlear fibres of the auditory nerve come into direct relation with each hemisphere, although Lichtheim does make an assumption to that effect.[23] On this subject of the intra-cerebral distribution of auditory fibres Foster says[24] the evidence derived from "secondary degenerations" "suggests that the path of auditory impulses is along the cochlear nerve to the lateral fillet of the crossed side, and so by the posterior corpus quadrigeminum and median corpus geniculatum to the cortex of the temporal lobe of that crossed side." Still, this distribution cannot yet be considered quite settled, so that, as Foster adds, "the matter needs further investigation."

The probabilities are, however, that each auditory nerve is indirectly connected with each hemisphere through the intermediation of commissural fibres between the two upper temporal and other convolutions in each temporal lobe, constituting the cortical seat of this endowment—such commissural fibres forming part of the corpus callosum.[25] In this way, therefore, a provision exists for the conjoint activity of the two hemispheres in connexion with the sense of hearing. In healthy persons auditory impressions pass equally to the two sides of the brain, and it is commonly supposed that minute differences in intensity of the impressions, dependent upon the source of the sound in relation to us, enable us principally to judge of the direction whence the sound emanates. Although we have no distinct proofs other than those of an analogical order that the general auditory centres are connected by commissures, we have proof that the specialised portions of them known as auditory word-centres must be so connected. Had it not been for the existence of such a connexion word-deafness would result from absolute deafness in the right ear (whether due to labyrinthine or to middle-ear disease), owing to the left auditory word-centre being cut off from all afferent impressions, as I pointed out some years since.[26] We know, however, that this does not occur; therefore impressions must reach this centre through the left ear, the right auditory word-centre, and thence across the commissure in the corpus callosum. And the fact that in such cases the comprehension of speech seems not to be diminished would point, I think, to the probability that the right auditory word-centre is about as well developed as the left on its receptive side.[27] And if that be so, is it to be supposed that it would remain functionally inert, save in the case of the accidental supervention of right-sided deafness?

Clinico-pathological investigations have long since taught us in an unmistakeable manner that the right auditory word-centre usually exercises (in right-handed persons) little influence upon the glosso-kinæsthetic centre of its own side; and now I would urge that new clinico-pathological observations should strongly incline us to believe that it must to some extent coöperate with the left auditory word-centre in the excitation of Broca's region for the production of articulate speech. We have seen that instances of paraphasic speech in cases of word-deafness associated with word-blindness are only capable of being explained in accordance with some such hypothesis, and there is the additional fact that speech has been found to be so much worse (with one exception) as to be quite unintelligible when both the auditory word-centres have been destroyed.

A difficulty that presents itself in connexion with such views as I have just been expressing is to account for the non-production of any amount of word-deafness from disease of the right auditory word-centre alone. It might be thought that even if the left auditory word-centre exercises an altogether preponderant influence in connexion with the comprehension and the production of speech, still the destruction of the auxiliary right auditory word-centre ought to produce effects of some kind, of a temporary if not of a permanent nature. Extremely little evidence, however, is available upon this subject, and it is one to which most careful attention should be given in the future.[28] We know, of course, that in left-handed persons the predominant activity of the auditory and the visual word-centres is in the right hemisphere, and that consequently in them we may get as a result of lesions in this hemisphere either word-deafness or word-blindness or both, just as we may get aphasia either alone or in association with left hemiplegia. Such cases of so-called "sensory aphasia" due to lesions in the right hemisphere have been recorded by Kussmaul[29] and also by Bernheim,[30] and there are doubtless many others. There was also a typical case of amnesia verbalis due to a right-sided lesion recorded by Trousseau.[31]

In what I have said hitherto I have only been contending

[23] Loc. cit., p. 483.

[24] Physiology, fifth edition, 1890, p. 1089.

[25] The anterior commissure seems mainly to connect the convolutions of the tip and under surface of the temporal lobe, so that it is more probable that its upper and posterior regions should be brought into structural and functional relation through fibres of the corpus callosum.

[26] Paralyses: Cerebral, Bulbar, and Spinal, 1886, p. 267.

[27] On this subject see what has already been said towards the end of the last section but one of the first lecture.

[28] What has just been said concerning the right auditory word-centre applies almost equally strongly to the right visual word-centre. We want to know also to what extent and for how long the comprehension of written and printed words is impaired by destruction of the right angular gyrus and supra-marginal lobule.

for the existence of another special illustration of a general principle which has previously been strongly advocated by others—namely, that of the double representation of movements in each hemisphere of the brain. Indeed, for many years Hughlings Jackson has gone further still, and has advanced the speculation[32] "that all parts of both sides of the body are represented in each half of the brain." Definite evidence on this subject was brought forward by Goltz, who, at the Physiological Congress in Basel in September, 1889, showed a dog from which almost the whole of the left hemisphere had been removed, and from whose behaviour, as demonstrated to the Congress, he felt able to announce the following important conclusions[33]: "Each cerebral hemisphere is in connexion with the voluntary muscles of both halves of the body. It appears, however, that the connexion between one cerebral hemisphere and the muscles of the opposite half of the body is more convenient than that on the same side. Hence a dog whose left hemisphere is destroyed prefers to use the left paw, because the will impulses from the right hemisphere flow by more convenient paths to the left limbs." He showed that sensibility was also present, and only somewhat impaired, in the right limbs of this dog. On the death of the animal the brain was removed, and was subsequently submitted to a most thorough examination by Langley and Grünbaum, who, at the conclusion of their report, say[34]: "We have seen that in this dog there was on the left side no part of the cortex remaining except a small portion of the hippocampal convolution, and a little grey matter round the optic chiasma; that the left corpus striatum had been removed, and that the nerve cells of the left optic thalamus had degenerated. Notwithstanding this, it appears from Professor Goltz's account that the animal retained voluntary power over all its muscles and could feel in every part of its body." So far as the production of movements is concerned, these results are harmonious with the well-known results obtained by Franck and Pitres,[35] who, after removing the so-called motor cortex on one side in a dog, found on faradaisation of the opposite cortical region that a convulsion was produced which involved first the limbs of the opposite side and then those of the same side of the body. Although this evidence tends in the same direction, it is not nearly so conclusive as that of Goltz.[36]

There is likewise actual evidence tending to show that in man also all movements are to some extent represented in each hemisphere of the brain. The representation of bilateral movements, as Broadbent originally pointed out, is commonly pretty equal, whilst that of limb movements is very unequal, being strong for the independent movements of the opposite limb and weak for the corresponding movements on the same side of the body. In support of this double cerebral representation there is the well-known fact that in hemiplegia some amount of paresis exists also on the opposite side of the body (that is, on the side of the brain lesion). There is also the well-known fact that in cases of large lesions in one hemisphere occurring in early life defects of sensibility are often even more thoroughly recovered from than the motor defects.[37]

What has already been said tends to show that bilateral arrangements of different kinds exist in the brain more or less analogous to that which I now postulate, namely, that Broca's centre is connected with both auditory word-centres—very intimately with the centre of the same side, and less intimately with that of the opposite side. The fact, moreover, that there are half-vision centres only in each hemisphere would seem to make it highly probable that for the voluntary performance of movements of one hand and arm, as in writing, there must in undamaged brains also be concurrent activity of these two centres brought to bear upon the cheiro-kinæsthetic centre during the conception and voluntary initiation of the movements. It has long been known that a functional activity of the visual centre is as essential for the conception and initiation of voluntary limb movements as a functional activity of the auditory centre is for the initiation of the voluntary movements concerned with speech. It would seem, therefore, as if in each case we have double auditory or double visual centres exercising their influence upon a kinæsthetic centre in the left hemisphere, in which speech movements have been registered in the one case and writing movements in the other.

The existence of the kind of nervous arrangements that I have been endeavouring to indicate in the two hemispheres would clearly necessitate the presence of numerous fibres in the corpus callosum having an oblique direction, in addition to those that are more directly transverse. It is well known that for long Meynert's view was generally accepted, to the effect that the fibres of the corpus callosum only serve to connect similar regions in the two hemispheres. By the careful study of the course of "secondary degenerations" in the corpus callosum resulting from lesions of different parts of the cortex Sherrington has, however, shown that this was an erroneous view. He has found[38] that not only similar but dissimilar parts of the two hemispheres are connected through this commissure. In regard to some inquiries of mine concerning this subject Sherrington writes: "My evidence was in part, as you suggest, the obliquity of the fibres, and also in part the spreading of them. ..... I found the degenerations from even circumscribed lesions of the fronto-parietal cortex spread considerably, especially after crossing the corpus callosum. I saw nothing at all incompatible with what you urge, but anatomically everything in favour of it."

There is another point of great interest in this connexion, and that is the greatly increased development of the corpus callosum in man as compared with that in the brain of the great man-like apes. We have it on the excellent authority of the late Professor Marshall[39] that the bulk of the corpus callosum, in proportion to the size of the brain, is twice as great in man as it is in the chimpanzee. It is only fair to assume that this relatively enormous increase in the comparative bulk of the corpus callosum is due in large part, either directly or indirectly, to man's acquirement of language and all the mental and moral development that has grown out of it.

(4) DEFECTS RESULTING FROM ISOLATION OF THE LEFT AUDITORY WORD-CENTRE.

A clinical condition is produced by the isolation of the left auditory word-centre—that is, by the cutting it off from all its afferent fibres—which was first described by Lichtheim in 1884,[40] upon the basis of a single case of word-deafness that seemed to differ from all others that had been previously recorded. To this condition Lichtheim gave the name of "isolated speech-deafness." It has been spoken of also by Wernicke as "subcortical word-deafness," whilst lately a similar condition has been described by Dójerine (who seems to have been oblivious or unaware of Lichtheim's case) under the name of "pure word-deafness." The state itself is simple enough, though an extremely interesting one. It is the condition of a partially deaf man, the deafness being not general, but limited to word-deafness. The patient can hear ordinary sounds, though more or less badly, he can talk correctly, can write correctly, can read aloud, and understand what he reads. His three disabilities are that he is unable to comprehend spoken words, and that he is consequently unable either to repeat words or to write from dictation.

I cannot agree with the pathology of the affection as given by Lichtheim or with that advanced by Dójerine. Lichtheim says[41]: "Both ears are capable of receiving and transmitting excitations of speech, but intelligence of language is bound up with the activity of the left hemisphere only, so both acoustic nerves must enter into relation with the latter." Thus the affection we are considering, he adds, "can obviously come into existence only if the irradiations of both acoustic nerves in the left temporal region are broken through." He concludes that the union of these two tracts takes place in the cerebral hemisphere above the level of the

[36] It has been shown by Sherrington and others in their studies of "secondary degenerations" that some of these double motor effects may be accounted for by the distribution in the cord of the fibres of the pyramidal tracts. It is known also that Broadbent explains some of the bilateral movements by reference to commissures existing between functionally related bilateral centres in the cord. But the voluntary movements of the right fore-paw in Goltz's dog must have implied the development in the only existing right hemisphere of the animal of all the nervous arrangements needful for the "conception" of separate movements in this right limb, that is, the passage to it and registration of kinæsthetic impressions from this limb, as well as the bringing of this centre into relation with the visual centre, in the manner that would be needful for the production of its voluntary movements.

Hosted by Google

internal capsule, and he believes it to occur somewhere in the white matter of the temporal lobe. A lesion in this situation, therefore, cutting off, as he assumes, the afferent fibres of both auditory nerves on their way to the left auditory word-centre, is the explanation that Lichtheim gives of the production of "isolated speech-deafness." Déjerine's view is still less satisfactory, as he speaks only of a severance of one set of afferent fibres proceeding to this centre.[42]

In regard to these explanations it may be said that the view of Déjerine is certainly insufficient, since, as I have already observed, it is well known that the cutting off of the afferent impressions going to the brain from the right ear alone does not give rise to word-deafness. Lichtheim's explanation, on the other hand, is unsupported by any anatomical facts showing the distribution that he assumes to exist, which would really be that of a semi-decussation of the auditory nerves, since, after speaking of his imaginary arrangement on the left side of the brain, he adds in a footnote, "a similar distribution must obtain in the right hemisphere." Both Lichtheim and Déjerine seem to think that the right auditory word-centre is either non-existent or possessed of no functional activity, and consequently that it is not brought into relation with the left auditory word-centre. They seem also to hold similar views as to the absence of a visual word-centre in the right hemisphere. If these views were correct, surely such convolutional regions in the right hemisphere ought to show some distinct diminution in size and development as compared with those of the left side. But no one as yet seems to have noticed anything of the sort.

There was no necropsy in Lichtheim's case of "isolated speech deafness," and from the particulars given it seems clear that the patient was generally rather deaf, altogether apart from his word-deafness. Thus my interpretation of this case some time since, after a careful study of its details, was that there probably existed pretty complete deafness on the right side, cutting off the left auditory word-centre from its proper incitations, whilst the slight sudden brain attack that is recorded to have occurred in June, 1882, may in some way have destroyed the commissural fibres connecting the left with the right auditory word-centre. In this way we should have the isolation of the left auditory word-centre brought about without the necessity for postulating the existence of any hypothetical and altogether unproved distribution of the auditory fibres within the brain. We should, in fact, have to do with a man partially deaf, capable of hearing noises only, but not able to perceive the meaning of spoken words—owing, on the one hand, to the complete isolation of the left auditory word-centre from all sounds; and, on the other, to the inadequacy for this purpose of the right centre alone, because of the imperfect development of associational fibres in connexion with speech functions in this hemisphere. This view has since been rather confirmed by the record of another case by Sérieux,[43] in which it is definitedly stated that the patient was absolutely deaf on the right side, as a sequence of an old otitis. The following are a few brief details concerning this case.

CASE 31.—The patient was a woman, aged fifty-one years. She had been suffering from partial word-deafness for six years. There was a complete absence of word-blindness, of motor aphasia, and of agraphia. Her hearing was normal on the left side, but absent on the right by reason of an old otitis. There was musical amnesia, the patient being unable to recognise or to sing certain airs. There was incomplete word-deafness; and writing from dictation was defective. There was slight paraphasia and paragraphia in spontaneous speech and writing. Comprehension of written language was slightly affected. There was progressive development of symptoms; especially subsequent to another slight cerebral attack, after which the word-deafness became complete and the power of writing from dictation was lost. Her spontaneous speech and writing still remained incorrect. Reading aloud was possible, but most frequently without comprehension of what was read.

Strangely enough it has been found that a very similar clinical combination may be produced in quite a different way, as may be seen by reference to the very remarkable case, previously cited from Pick, of destruction of the auditory word-centre in each hemisphere. Here the clinical condition was almost identically the same. There was even a certain amount of general deafness, though it was not due to middle-ear disease, nor did it seem to be definitely localised to one side. As I have already said, this case seems absolutely inexplicable unless we are to suppose that the patient was a "visual" who could speak, write, read aloud, and understand wha he read, mainly through the activity of the visual and the kinæsthetic word-centres—at all events without the coöperation of the auditory word-centres, seeing that these were destroyed. The case shows, moreover, that general deafness does not result from destruction of these special word-centres even in both hemispheres. The patient's general hearing power was defective, though far from lost.

These are the only three cases of "isolated word-deafness" known to me.[44] It will be seen from what I have said that this rare group of symptoms is capable of being induced in two very different modes—just as we shall find subsequently that what Déjerine has called "pure word-blindness" may also be produced in two different modes, and that the modes are analogous in the two cases. Pick was fully aware of the very unusual nature of his case. He recognised that it could not be a case of sub-cortical word-deafness of Lichtheim's and Déjerine's type, though he was not prepared to advance any other interpretation. Mirallié, however, has been so very uncritical as to cite it[45] as an example of Déjerine's type, notwithstanding the fact of the existence of the double cortical lesions occupying the sites of the auditory word-centres.

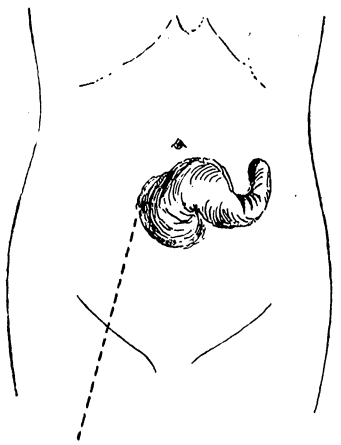
TWO CASES OF

INTUSSUSCEPTION SUCCESSFULLY TREATED BY LAPAROTOMY; ONE PRESENTING SEVERAL UNUSUAL FEATURES.



BY R. LAWFORD KNAGGS, M.C. CANTAB., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE LEEDS GENERAL INFIRMARY.

OF the following cases the first is of special interest, more from the suggestive nature of some of the symptoms than from the numerous risks which the little patient successfully surmounted.

CASE 1.—A girl, aged eight years, the subject of a perfectly controlled right inguinal hernia, was admitted into the Leeds Infirmary under Mr. Mayo Robson on Aug. 7th, 1896, and in his absence came under my care. Seventeen days before, when at school, she was seized with pain in the abdomen during defecation. From that time vomiting had been constant and pain intermittent. Actions of the bowels were obtained on the sixth and eleventh days, and the motions contained neither blood nor mucus. Though flatus was passed occasionally, the abdominal distension had gradually increased. Two days before admission all her symptoms were aggravated and the obstruction became apparently complete. When first seen on the evening of Aug. 7th there was great abdominal distension and general tympanites. Vigorous visible intestinal movements could easily be excited, but no tumour could be felt. The tongue was moist and furred, the pulse was 140, and the intelligence was clear. The condition to be dealt with was obstruction, not strangulation, and the patient's condition was critical; so enterotomy, to tide her over the immediate danger, was decided upon in case there was any difficulty in finding the cause of the trouble. On opening the abdomen in the middle line the distension produced by the enlarged small intestine was so tight that the utmost difficulty was experienced in insinuating the fingers between it and the parietes to explore the hernial orifices and the cæcal region. Nothing suspicious was detected, and to have done more some of the coils of bowel must have been brought outside the abdomen, a proceeding which I feared would be likely to add very greatly to the severity of the operation. A knuckle of small intestine was therefore selected and fastened in the lower angle of the wound, which was then closed. The bowel was opened at once and a Paul's tube inserted. The operation did not take long, and the patient stood it well. Perfect relief was obtained, and the patient's general condition quickly improved, but she remained subject to spasms of pain—less severe, certainly, than before, but sufficient to wake her during sleep and to call for the administration of opium at times. When the distension had completely

Hosted by Google

subsided a distinct thickening could be felt in the right iliac and lumbar regions, and the resonance over it was much impaired. The character of the swelling varied, being sometimes soft and almost imperceptible, and at other times (especially after examination) hard and distinct, when the abdominal surface became slightly raised, as if the bowel underneath were in excessive peristalsis, and pain was complained of in the tumour and down the right thigh and over the instep. The diagnosis of intussusception was made, and it was soon evident that it was permeable, for on the 17th there were two evacuations by the rectum, one of which was slightly streaked with blood. Some delay in dealing with the tumour now occurred in attempting to improve the surface of the abdomen, which had become raw over a large area. The last plan tried was the insertion of a Paul's tube to lead away the fæces through the dressings, but one night it slipped in and was lost. For the next thirty-six hours the patient was kept lying on the left side to prevent the right from being soiled, and on Sept. 3rd the following operation was performed under A.C.E. mixture. The artificial anus was plugged and the abdomen, especially the right side, was carefully cleansed with soap and carbolic lotion, and then with benzine, and finally washed with carbonate of soda solution and soap. Pieces of gauze were then spread over the artificial anus and the raw surface on either side of the intended incision. This was four inches long and extended from one inch below the costal margin to a point inside the anterior superior spine, external to the right linea semilunaris. On opening the peritoneum the large bowel was found with the small intestine invaginated into it. At this point there was some congestion, and strands of lymph were stretched between the two portions of bowel. The cæcum and vermiform appendix were not involved in the tumour, which was about ten inches long. The apex of the intussusception was brought to the surface, and by pressing up the lower end of the invagination reduction was quite easily accomplished; numerous bands of stringy lymph, which united the two opposed serous surfaces, being ruptured as the outer layer peeled down from the tumour. The invaginated bowel was small, much contracted, and reddened, and showed the results of plastic peritonitis; the mesentery was congested and puckered by adhesions. About six inches above the ileo-cæcal valve a thickened lump projected from the inner surface of the bowel opposite to the mesenteric attachment. This was no doubt the presenting portion of the invagination, which was of the ileo-colic variety. The Paul's tube was sought for and found, and as it could not easily be passed back through the artificial anus it was passed on through the bowel that had been reduced and left at the top of the ascending colon. The wound was sutured in layers and dressed with collodion and gauze. At the moment when the tumour was brought to the surface and put somewhat on the stretch and during its manipulation the patient became very pale and collapsed, but an ether injection helped her, and at the close of the operation her condition was satisfactory. From this operation the child made a good recovery, except for some suppuration about the wound, which eventually became soundly healed. She was completely relieved of "the pain in her inside," and the bowels acted by the rectum occasionally up to Sept. 23th, when a spur had formed. On Sept. 13th, as she had been complaining of spasmodic pains, she was anæsthetised to see if the Paul's tube could be detected. It was found where it had been left. The opportunity was taken to close the artificial anus by dissecting the edges down, inverting and suturing them. The union had completely broken down on the 18th, but the fæces had passed along the colon for at least three days, and the Paul's tube came away after an injection on Oct. 6th. In October a remarkable series of events took place. For some time the child had been suffering from colicky pains, for which it had been necessary to give opium occasionally. These pains increased in severity, and by Oct. 20th a protrusion of the bowel had appeared from the artificial anus on seven occasions, usually after an exacerbation of the pains. It generally attained a length of three or four inches, was usually in a state of active peristalsis, was firm and solid, and in appearance was exactly like the intussusceptum of an invagination. Its reduction was on several occasions so difficult that an anæsthetic had to be given. I was only fortunate enough to see the protrusion once, when it lay upon the surface of the abdomen with the sigmoid curve represented in the sketch. An inability to obtain a probe at the moment prevented me from settling its real nature—whether prolapse or intussusception—before reducing it; and, unfortunately, I never had another opportunity, nor am I aware that the investigation was ever made. These protrusions came sometimes from the upper, and on two occasions at least from the lower, segment of bowel. This point was settled by the escape of fæces from the apex in some instances, and in others, when the lower segment was affected, by their discharge at the root of the outgrowth. On the latter occasions the prolapsing gut would disappear down the aperture on one side of the spur, whilst fæces would pour away from the opening on the other. But a still more interesting fact was noticed on Oct. 16th, when the swelling appeared from the upper

portion. The Sister attempted to return it, but only succeeded in diminishing it by half an inch. When Mr. R. H. Trotter arrived twenty minutes later it was about an inch long. As soon as it was uncovered spontaneous reduction began and the tumour disappeared without being touched. It was in active peristalsis the whole time, and the reduction took place from the end, the outer layer being continually inverted at the apex until the whole had disappeared. On Oct. 20th, with some misgiving in consequence of this peculiar behaviour of the intestine, I proceeded to perform enterectomy for the closure of the artificial anus. The edges of this aperture were first separated, and then carefully closed over a plug of gauze with a continuous suture. The raw abdominal surface was next cleaned with the same precautions as before, and covered with gauze around the intended incision. The abdomen was then opened, the intestine isolated from its attachments to the parietes, and a loop containing the artificial anus was clamped with india-rubber tubing. Two inches of intestine including the opening, were cut away, and the divided ends sewn together over a Mayo Robson's bobbin. The wound was then closed. Nothing was found in the appearance of the bowel close to the part resected to explain the tendency to protrusion. The patient did well uninterruptedly. Ether sickness persisted for thirty-six hours and then fluid food was retained. Nepenthe was twice ordered for pain connected with the operation, but after the first day it was evident that the child was greatly relieved. She slept peacefully, and was not roused by spasmodic pains as she had been before the operation, even when taking opium regularly—indeed, she did not complain of pain at all. She was happy and cheerful, and gained flesh daily. The bowels were moved on the second day and have acted regularly since. The bobbin came away on the fourth day. The wound was healed on Nov. 11th. The patient was up on the 14th and went home on the 21st, and remains well. I gratefully acknowledge the help received in the course of the case from several of my colleagues, the resident surgical officer (Mr. Basil Hall), and particularly from the house surgeon (Mr. R. H. Trotter), upon whose careful observations and notes much of the interest of the case depends.

CASE 2.—Late in the evening of Nov. 14th, 1896, I was asked to see a boy, aged eight years, who had been admitted into the Leeds Infirmary under Dr. Chadwick on the previous afternoon. He was suffering from all the typical signs of acute intussusception. The vomiting, which had been severe so long as nourishment had been taken, had moderated.

Hosted by Google

The pain had kept him awake all the previous night and at times was so severe as to make him cry out. Numerous evacuations containing blood-stained mucus and no fæces had been passed, and a tumour could be felt just below the splenic region. This was sometimes soft and at others hard, and when in this latter condition it formed a visible swelling as big as an orange. There was no abdominal distension, the pulse was 130, and the patient was in fair condition, though the onset had occurred with sudden pain before breakfast on the 10th, and the symptoms had been acute from the commencement, the vomiting and bloody stools beginning almost directly after the first attack of pain. At midnight, therefore, on Nov. 14th, he was put under A. C. E. mixture, and inflation was performed with a Higginson's syringe. As this proceeded, and the large intestine became distended, the tumour was excited to very powerful peristalsis. It gradually appeared as a curved mass with one extremity above and to the right of the umbilicus, and the other dipping down into the left lumbar region. It stood up on the surface of the abdomen as a sharply defined, firm, bossy swelling of considerable elevation. Its length was quite six inches, but it was subsequently found that the whole of the tumour could not have been visible. As inflation progressed its only effect was to make the mass stand up more vigorously; so it was discontinued, when the swelling gradually faded away. After the usual preliminaries the abdomen was at once opened by a median incision three inches long, beginning a little above the umbilicus. The descending colon was found at once and traced up until the tumour could be felt. The fingers of the right hand in the abdomen then compressed the ensheathing bowel upon the invagination, and, gradually, inch by inch, the colon came down from it as the apex was pushed up. When some inches had been drawn down in this way the presenting portion could be brought into the incision and its dark colour recognised through the healthy bowel covering it. The neck was now sought for by the left fingers and found deeply situated against the spine and very firmly fixed there. The tumour at this stage felt to be six or seven inches long and much thicker than the lower part when first grasped, as if the intussusception had been simply crowded up into a smaller space. However, as the process was continued the tumour was felt slowly to diminish, and when only about one and a half inches remained it became more moveable but more difficult to unroll. It was now easily brought into the wound and the disinvagination completed in sight, some difficulty being caused by the stiffness of the presenting part. This was a disc-like portion of the bowel rather larger than a shilling, situated away from the meso-colic attachment, convex towards the lumen, and concave externally. It was so stiff that it felt as if any attempt to press out the concavity would crack it. This disc was situated in the large intestine, which, both above and below, was much thickened and altered in colour from the congested interior showing through the peritoneal covering, which also presented signs of inflammation. The intussusception was therefore of the colic variety, but no attempt was made to learn how far the presenting part was from the ileo-cæcal valve. Several ruptures of the peritoneal coat of the bowel were produced by the manipulations, but these were not touched, and as soon as the reduction was completed, and the soundness of the part last unrolled ascertained the abdomen was closed. The proceeding had been carried out almost entirely inside the abdomen, where the distension produced by the inflation had proved to be somewhat embarrassing. With the exception of an attack of bronchitis following the operation, the subsequent record is one of steady convalescence. Relief was complete. Vomiting stopped, fluid nourishment was retained, and a natural motion was passed within eighteen hours of the operation. A dull area was present in the umbilical region for some time and probably corresponded with the position of the thickened bowel. Healing was complete by Dec. 20th, the child went home on Jan. 2nd after the Christmas festivities, and he remained well at the time of writing.

Remarks.—When a condition such as intussusception shows so high a percentage of cases as 62 in which no obvious exciting cause can be detected it presents at least a fair field for speculation. According to the figures given by Mr. Treves [1] about half the remaining 38 per cent. owe their origin to some local trouble, whilst some ailment, the influence of which is doubtful, is usually associated with most of the others. When no gross explanatory lesion is forthcoming it is only natural that we should turn to the nervous system for inspiration, for the movements of the intestines are under the influence of a somewhat complicated piece of nerve mechanism, a description of which is given in Foster's "Physiology," Part ii., p. 491. To anyone interested in the etiology of intussusception the section is very suggestive, and not the least so that portion of it which applies more particularly to the intussusceptions of the dying. It is sufficient for my purpose, however, to remind the reader that stimulation of the vagus gives rise to powerful peristaltic movements, or increases those previously going on, and that efferent impulses along this path may be excited by afferent ones, such as emotion, fear, or chill—to mention some which are matters of personal experience to most people. This reflex phenomenon is no doubt more readily produced in some than in others, and even in the same individual the ease with which it is excited may vary considerably and be largely influenced by the state of health and the consequent tone of the nervous system. It is of importance here because it is sufficient to explain those violent and irregular intestinal movements which are regarded as the predisposing causes of an invagination; and the fact that the subjects of intussusception noticeably belong to the category of weakly or delicate children, in whom the nerve functions are likely to be more than usually sensitive, does not diminish the probability that the exciting cause of many an invagination may be found in some peripheral irritation.

Now, there are some points in the first case that have a marked bearing upon this matter. First, for the sake of clearness, let it be understood that the protrusions which came from the artificial anus will be regarded as complete prolapses of the bowel, because such a condition would be less remarkable, and consequently more probable, than an intussusception.[2] The presence of the Paul's tube might have been thought sufficient to account for those manifestations had not the painful peristalsis and consequent prolapses increased in severity and frequency after its expulsion. Circumstances, however, point strongly to the conclusion that all the trouble was due to the frequent irritation of the raw abdominal surface by contact with the intestinal contents, for as soon as the enterectomy was performed and this could no longer occur, the painful peristalsis became a thing of the past. The association between prolapse and intussusception is so close (and particularly so in this instance, as will be seen from what is said below) that an influence which can lead to the one is probably quite capable, under suitable conditions, of giving rise to the other.

In the light of the present case there is nothing difficult to understand in that of a child, aged five years, mentioned in Mr. Treves's monograph, who died with an intussusception four days after a burn,[3] nor in the six cases collected by Leichtenstern, in which symptoms appeared after exposure to cold. If this reasoning is correct it should excite no surprise that the etiology of so small a number of cases of intussusception is cleared up by post-mortem examination, for it is more than probable that the real exciting cause of not a few is some external influence, often so slight as to be easily overlooked, or of such a temporary character as to be incapable of recognition by the children who are affected.

Mr. Golding-Bird [4] records a case in which a retrograde intussusception made its appearance on the surface of the abdomen through a patent Meckel's diverticulum. The cord had separated four days after birth and fæces had been discharged from the navel from that time. Mr. Golding-Bird refers to a paper by Barth,[5] giving about a dozen instances of prolapse and one of intussusception under similar conditions. These cases have a striking resemblance to the one under discussion, but the point to which I would draw particular attention is that the same form of surface irritation was certain to have been present in all.

The strong points of likeness that exist between the prolapses and the invagination in this case are due to the particular variety to which the latter belonged—viz., the ileo-colic. Mr. Treves has pointed out that this form originates in a different way from any other. It begins as a prolapse

Hosted by Google

of the ileum into the ascending colon, which increases so long as the length of the mesentery permits it. When the ileum can prolapse no further the process changes, the cæcum and ascending colon being gradually inverted and the continued growth of the tumour taking place in the usual way. Here the second stage had not begun.[6] It is evident from this that in their nature and mode of origin the two conditions were practically identical. This identity is of special interest when viewed in connexion with the unassisted return of the prolapse which was witnessed upon one occasion. If a prolapse through an artificial anus can recede of its own accord, one lying loose in the capacious ascending colon can probably do the same. The possibility of spontaneous reduction of an intussusception is admitted and thought to occur not unfrequently, though from the very nature of the case actual proof is wanting. But the method by which it is accomplished can be gathered from this observation. A vigorous peristalsis occurs in the entering tube of bowel, and as the wave passes downwards succeeding lengths of longitudinal fibres contract and invert successive portions of the returning layer at the apex. In this way the intussusceptedbowel diminishes, and is finally reduced. If the methods of artificial and spontaneous reduction are compared an interesting difference is revealed. The surgeon disengages the bowel by peeling the sheath downwards off the intussusceptum, at the expense of the upper end of the returning cylinder, until reduction is completed; but the intestine produces the same result by the intrinsic action of the entering layer, which rolls the returning cylinder inwards at its lower end until the whole of it has disappeared and the invagination no longer exists.

Attention cannot fail to be attracted by the fact that in Case 1 reduction was easy of accomplishment after symptoms had existed for forty-four days. In Mr. Hutchinson's well-known case disinvagination was safely performed at the end of a month. But neither of these approaches the case recorded by Dr. Handfield-Jones and Mr. Page,[7] in which an invagination was reduced after a probable duration of three months.

The variety of the intussusception and the diversion of the fæces were no doubt the two contributing factors to this result in my first case. Had the intussusceptum been firmly grasped by the sheath, instead of lying rather loosely in it, the congestion would have been much greater and the inflammation of the opposed serous surfaces more intense and of earlier date; whilst the artificial anus probably prevented the continued growth of the tumour by the inverting of the cæcum and ascending colon, a circumstance that would quickly have been followed by acute symptoms. It has been pointed out that the absence of bloody stools may be due to strangulation of the invagination, and that consequently that important symptom is not to be relied upon as a trustworthy indication of the condition of the bowel. But if it be considered in association with the constitutional symptoms and condition of the patient it is a distinct help. If there be no bloodstained discharge from the rectum in a case of intussusception, it probably means either that the blood flow through the tumour has been suddenly stopped or that it has not been seriously affected. In the former case the usual signs of strangulation will quickly make their appearance; in the latter they will not. In this instance the absence of a bloodstained mucous discharge and of excessive tenderness about the tumour led me to hope that the opposed serous surfaces would not be found inseparable.

One other point is worth mentioning. On one occasion when the first patient was under an anæsthetic I introduced my finger through the artificial anus to feel the tumour bimanually, and was astonished at the facility it gave for exploring the abdominal cavity. So freely could the finger be moved about in all directions that for a moment I feared it might have got inside the peritoneum. The intussusception could be felt from its neck in the right iliac fossa to its os uteri-like apex near the gall bladder. The left loin and iliac fossa could be examined with equal ease, and no doubt the pelvis and higher abdominal regions could have been similarly investigated had I not felt that it is sometimes wise to set a limit to curiosity.

HEPATIC FISTULA SUCCESSFULLY CLOSED AFTER SIXTEEN MONTHS.

BY D. M. MOIR, M.A. ST. AND., M.B., C.M. EDIN.,
SURGEON-CAPTAIN, INDIAN MEDICAL SERVICE.

AN Armenian, aged twenty-seven years, while employed in railway construction at Selangor in the Straits Settlements about the middle of December, 1893, began to suffer from what eventually proved to be an abscess of the liver. He was admitted into hospital at Perak at the end of January, 1894. Early in March he was transferred to the hospital at Penang, where he was operated on for an abscess of the liver. Six weeks later he was discharged apparently cured, the wound having closed. He sailed for Singapore, but the wound re-opened on the voyage, and there was a copious purulent discharge. On arrival at Singapore he went into hospital, and a drainage-tube was inserted. The wound was again healed by the end of June. After remaining six weeks longer at Singapore the sinus reopened and again began to discharge pus. Accordingly he sailed for Calcutta, and was admitted into the Presidency General Hospital on Sept. 4th, 1894. No antecedent history of dysentery or drink could be elicited. On admission he was in rather a reduced condition, weighing only 123 lb. The liver was of natural size, but there was a hepatic fistula discharging unhealthy pus in the eighth intercostal space and pretty far back in the infra-axillary region. On Sept. 6th the first attempt to close the sinus was made. An incision was made to explore for dead bone, but the ribs were quite healthy. After a little manipulation the fistula was found to be very narrow, slightly tortuous, and six inches long. Its track was dilated so as to admit a long and narrow drainage-tube. On the 10th the patient was transferred to my wards, and he continued as my patient until he finally left the hospital in October, 1895. Syringing with iodine lotion and insufflation with iodoform were tried, but ineffectually. Then on Sept. 28th, 1894, an inch and a half of the eighth rib was resected in the region of the fistula. The channel was over six inches, very narrow (admitting only a fine probe or a knitting needle), and had dense walls which felt almost cartilaginous in consistence. In its course the fistula traversed the pleural cavity (the pleura being adherent around it), the diaphragm, and a considerable thickness of liver tissue near the upper surface of the right lobe. The track was dilated gradually with some difficulty, until, finally, a cavity was reached. The finger could just reach this cavity; but it was estimated, with the help of instruments, that it was about the size of a hen's egg, and that it had thick walls. A collection of pus, caseous material, and sloughy tissue was removed by a long-handled Volkmann's spoon. A drainage tube having a diameter of three quarters of an inch was inserted. For the next two or three days the patient suffered from acute epigastric pain, nausea, and vomiting; but after Oct. 1st there was no further trouble. Up to the end of November his physical condition was good, and he weighed 138 lb., having gained over a stone; but the fistula would not heal, and at this time was two and a half inches long. Although the discharge had become scanty it frequently contained bile and mucus for several days at a time—and the bile seemed to retard healing. Various solutions were tried for syringing the fistula—e.g., carbolic acid, perchloride of mercury, boric acid, thymol, iodine, iodoform in ether, and sulphate of zinc. The tube was gradually shortened, then smaller tubes were substituted, and finally when the fistula narrowed a strip of lint was inserted. Bark and ammonia and hypophosphites were given, and on several occasions sponge grafting was tried, but nothing succeeded. In December he began to lose ground again, and the length of the fistula varied from three to four inches. The discharge contained flaky pus, occasionally bile, and tenacious glairy mucus. The wound was syringed twice, sometimes thrice, a day. This improved the character of the discharge. A solution of nitrate of silver was once injected along the track; but it proved injurious, causing acute pain in the epigastrium, vomiting of bile and mucus, and an increased discharge of bile from the wound. Sulphate of copper was also applied without material benefit. On Dec. 18th an incision was made through the former cicatrix, and the fistula was slit up and dilated. The cavity

Hosted by Google

was now smaller and more shallow, and so could be better explored by the finger. The dense connective tissue lining the walls of the fistula and cavity for the entire length of the track was thoroughly scraped with a Volkmann's spoon and the débris removed; then the entire raw surface was well swabbed with a solution of chloride of zinc (forty grains to the ounce) and a large drainage tube was introduced. This operation was not attended with any serious hæmorrhage. That night and next day there were cough, bilious vomiting, and epigastric pain. The drainage-tube seemed to irritate the diaphragm, but after the first two days he had little pain or discomfort. In January, 1895, he began to improve again. The fistula became smaller and the discharge less; but still the dressings were often bile-stained. Quinine and iron, nitro-muriatic acid, and nux vomica were administered. During February his general health was excellent, but the fistula remained much the same. Syringing and insufflation were discontinued, and a probe covered with cotton-wool and dipped in compound tincture of benzoin was daily inserted in the fistula. This proved more efficacious than anything hitherto tried; still, the track would not close, and the discharge contained bile at intervals. In March the same treatment was continued and the discharge almost ceased, but the fistula was still nearly two inches in depth, so on March 22nd he was sent on a voyage to Singapore in the hope that the change and sea air might prove beneficial. He returned to hospital on May 24th. The trip had apparently done him more harm than good. He looked worse and said he had felt miserable all the time he was at sea. The sinus was two and a half inches long and had been constantly discharging bile, mucus, and pus. His weight was 131 lb. He was given a tonic mixture, the wound was dusted with alum and iodoform, and a dry dressing of perchloride of mercury was applied. Early in June minute particles of nitrate of silver were inserted into the fistula, which remained about two inches long and continued to discharge bile occasionally. His weight rose to 136½ lb. On June 8th a probe heated red-hot was introduced and the walls of the track were thoroughly cauterised. This was the only operation which was followed by fever, and the febrile reaction was severe. Next day his temperature rose to 102° F., on the following day it varied from 100° to 104 2°, on the 11th from 101° to 104°, and on the 12th from 101·8° to 105·4° F. He was very restless and suffered from intense headache, and the discharge was profuse, greenish, and viscid. On that day he developed acute orchitis and epididymitis without any obvious cause. This was treated by free leeching and an evaporating lotion. By June 18th the fever had quite left him and he again began to improve, but the fistula had increased to three inches. The right testis remained large, and on the 22nd fluctuation was discovered, and his temperature again began to rise. An abscess in the globus major of the epididymis was incised and drained. He was given a mixture of strychnine and iron, with sulphate of magnesia occasionally, and powdered boric acid was applied to the fistula and a dry dressing. Early in July an emulsion of eucalyptus oil was injected into the fistula, which was again two and a half inches long. The track began to contract rapidly, and by July 8th the fistula was occluded and there was no discharge. The fistula was soon firmly healed and subsequently gave no further trouble. He remained under observation until Sept. 16th, when he was discharged feeling perfectly well and strong. But four days later he was re-admitted suffering from an anal abscess, which was incised on the day after admission and the wound healed readily. He was finally discharged on Oct. 7th, 1895, at which time the scar of the hepatic fistula was quite firm and the liver seemed sound. He went to Burmah, and I have heard nothing more of him.

Remarks.—This case is of some interest owing to its obstinate course, to the number of operations performed, and to the intercurrent complications. The persistence for sixteen months of a hepatic fistula, after an abscess of the liver was opened, illustrates the evil of the too early removal of the drainage-tube. Probably, also, too small a tube was used in the first instance. For the drainage of an abscess of the liver the larger the tube the better, and there should never be any hurry to dispense with the tube. *Festina lente* is just as important a principle in the after-treatment of an abscess of the liver as is the avoidance of delay in operating when once the abscess has been diagnosed. Quite a variety of causes were at work to prevent the closure of the fistula—(1) There was the absence of surgical rest owing to the cavity and fistula having such close relations to the diaphragm, a muscle which is never at rest; (2) the course of the fistula was somewhat tortuous through the various layers of liver, peritoneum, diaphragm, pleura, intercostal muscles, and skin; (3) there resulted consequently an ill-drained cavity at the end of a long and sinuous passage, which would not heal owing to retained sloughs; (4) the escape of bile and mucus from time to time through the fistula caused irritation and retarded union; and (5) the chronic nature of the case tended to further the formation of a lining of dense cicatricial tissue in the walls of the fistula, which, until it was destroyed, of itself precluded the possibility of closure.

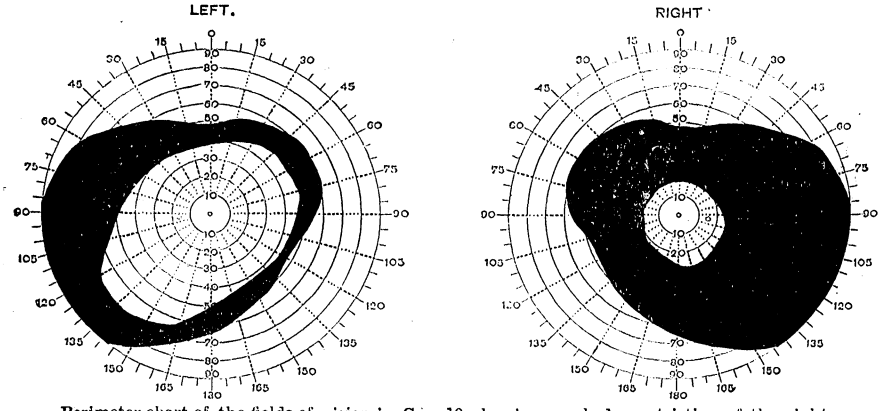
PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY, LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE, SCHOOL OF MEDICINE, EDINBURGH, ETC.

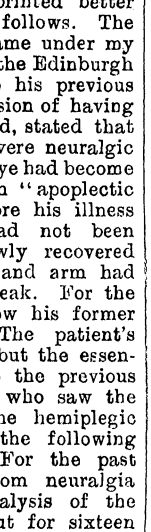
(Continued from p. 1080.)



CASE 9. *Complete motor aphasia, word-blindness, and agraphia; no obvious word-deafness.*—This is another case in which the patient could understand spoken language; in other words, in which there was no obvious affection of the auditory speech centre, but in which there were complete motor vocal aphasia, word-blindness, and agraphia. This condition was present from the first. The absence of word-deafness in an otherwise complete aphasia of rapid development suggests either (*a*) that in some persons the auditory speech centre is active on both sides, or (*b*) that a profound vascular lesion which completely destroys the functional activity of the visual speech centre, the motor vocal speech centre, and which produces complete agraphia, does not implicate the auditory speech centre. In commenting upon Case 8 I have already referred to this most interesting and important question. The notes of the present case are as follows. The patient, a man aged sixty-three years, was seen on Aug. 31st, 1893, suffering from slight right-sided hemiplegia and aphasia. On the 27th he had some difficulty in speaking and his wife noticed that he repeated some words two or three times. This passed off in the course of a few hours. The next day the difficulty in speaking returned and again passed off. He remained fairly well until the 30th, when he had a more severe attack. He completely lost his speech, the temperature rose, his head became very hot, and he wandered a little in his mind. Since then he had complained of numbness and weakness in his right hand and leg. On examination the right side of the face was found to be markedly, and the right arm and leg very slightly, paralysed. Mentally the patient appeared pretty acute. He seemed to understand everything that was said to him; he put out his tongue, moved his hand, leg, &c., when told to do so. The auditory speech centre did not appear to be affected, at all events in any marked degree. There was complete motor vocal aphasia. He could not even say "yes" and "no." There was complete word-blindness. Several simple questions were put to him in writing, but he manifested no sign of intelligence. The rough test seemed to show that there was right-sided homonymous lateral hemianopsia; but in the patient's aphasic and word-blind condition it was difficult to be sure of this. He was quite unable to write; although there was little (gross) loss of power in the right arm and hand he seemed unable to hold a pen or pencil securely. A week after my visit he became very much worse, the temperature rose, he seemed to suffer from headache, and the right arm and leg became completely paralysed. The attack was probably due to secondary inflammatory changes around the lesion. He slowly recovered from this condition. On Nov. 8th, 1894, his wife, who was consulting me about herself, reported that he was able to walk and had regained some power in the right hand. He seemed to understand everything that was said to him, but was totally speechless; he could not even say "yes" and "no." He could not understand written language. He could sign his own name, but could not write anything else. She doubted if he always made signs correctly. She thought he sometimes pointed in one direction when he meant another. Nevertheless,

Hosted by Google

he interested himself in his garden and grounds, and was constantly out of doors in fine weather, giving directions by signs, which were evidently intelligible, for the gardener did what he wished him to do.



CASE 10. *Left hemiplegia with paralysis of the muscles supplied by the right third nerve; word-blindness; paragraphia.*—This case is of considerable interest from the fact that the marked word-blindness and paragraphia were apparently the result of a lesion of the right hemisphere, though the patient was right-handed. I say apparently the result of a lesion in the right hemisphere, for in the absence of post-mortem verification it is impossible to be absolutely sure on this point. There may, of course, have been a double lesion—one in the right side of the brain causing the paralysis of the right third nerve and the left-sided hemiplegia, and another in the left side of the brain (left angular gyrus) causing the word-blindness and paragraphia. But this is unlikely. An interesting point in the case is the fact that the patient could read printed better than written characters. The notes are as follows. The patient, a man aged thirty-four years, first came under my observation in the out-patient department of the Edinburgh Royal Infirmary on Feb. 10th, 1886. As to his previous history, the patient, who gave me the impression of having been both intelligent and fairly well educated, stated that four years previously he suffered from very severe neuralgic pains in the head and the muscles of his right eye had become paralysed. Three years previously he had an "apoplectic attack" followed by left hemiplegia. Before his illness he could read and write well. He had not been able to speak well since. He very slowly recovered from this attack; the paralysis of the face and arm had entirely disappeared, but the leg was still weak. For the past four months he had been able to follow his former employment and to earn 15*s.* a week. The patient's memory was evidently very much impaired, but the essential accuracy of the above statement as to the previous history is confirmed by Dr. John Thomson, who saw the patient a few days after the onset of the hemiplegic attack, and to whom I am indebted for the following note, which was made at that time. "For the past twelve months the patient has suffered from neuralgia of the head. This was followed by paralysis of the right third nerve. The right eye was shut for sixteen weeks, the patient saw double; the rest of his face was not affected, and no other parts of the body were paralysed. The right eyelid has always drooped since the attack. Since the paralysis the patient has suffered from recurrent attacks of neuralgia in the head. On the morning of Jan. 26th, 1883, he choked while sitting at breakfast; he then 'took a shiver' and was put to bed; there was some difficulty in getting his coat off his left arm. During the afternoon the left side gradually became more paralysed; he spoke a little when roused, but he has never spoken clearly since. He lay for two days in a stupid condition, and seemed to have pain in the throat; he was very cross and irritable, and would not swallow. Three days after the attack he was able to speak quite intelligently and was not so irritable; had a dose of castor-oil; has refused to take everything since; he attempted to get up and go out; had to be held down in bed." His condition on Feb. 10th, 1886, three years after the original seizure, was as follows. The patient, who was right-handed, was well nourished. The gait was markedly paralytic, with much circumduction of the left leg. The left arm was slightly weaker than the right and the left side of the face seemed somewhat flatter than the right. There was some ptosis of the right eyelid; the patient could neither rotate the eyeball upwards nor downwards; the eyeball was not rotated inwards during efforts of fixation for near objects, but it was moved inwards—i.e., to the left—in association with the opposite eye—i.e., when both eyeballs were turned to the left. The patient said that he saw double on looking up. The right pupil was dilated and twice the size of the left; its outline was slightly irregular; it contracted, but not briskly, both to light and accommodation. Both the acuity of vision and the field of vision were considerably impaired in the right eye, much less so in the left (see Fig. 18). On ophthalmoscopic examination the retina surrounding the margins of the right disc was perhaps a little hazy, the disc a little paler, and the veins a little larger and more dilated than those in the left. The other special senses appeared to be normal. Both the deep and superficial reflexes were greatly exaggerated (knee-clonus and ankle-clonus) in the left paralysed leg, and considerably exaggerated in the right. Urination and defecation were normal. The sensibility of the skin to tactile and painful impressions seemed normal and equal on both sides of the body. The heart and kidneys appeared to be healthy. As to his psychical functions, memory seemed much impaired and the cerebration generally slow, but the patient seemed to understand everything that was said to him and did what he was told. His emotional faculties were under loose control; he laughed much too easily. He seemed inordinately amused at many of the tests which were applied in eliciting the foregoing particulars. With regard to his speech faculties, there was no motor aphasia. The articulation was somewhat slow, thick, and hesitating. There was no obvious word-deafness. There was considerable word-blindness. The patient seemed to be able to read printed (type) characters much better than manuscript. The printed words "the," "on," "of," "by," "hotel," "same," "each," and "Switzerland" were read correctly. The word "the," written as in Fig. 19, he said was three figures. When asked after a considerable interval to read the same word he said, "It is two strokes and a nothing." The word "on," written as in Fig. 19, he read correctly. The word "no" (see Fig. 19) he read as "nothing"; and as to the word "by" (see Fig. 19) he said after some hesitation, "It is b y; no, it is b e; no, by." When tested on another occasion he was unable to read the written words "the" and "of," while "by" he said was "baby." While being tested on this occasion he was obviously quite conscious of his defects, for he said, "I am like a daft man; before I spell that out now I forget what I began with." On another occasion he correctly read his own name, "Edinburgh," and "How do you feel?" but could not read the words "dog" and "cat" when written by me. There was marked paragraphia. His manipulative powers were unimpaired, but he

FIG. 18.

Perimeter chart of the fields of vision in Case 10, showing marked constriction of the right and some constriction of the left field, perhaps the result of former papillitis.

FIG. 19.

Hosted by Google

always introduced too many letters into his words. Even his own name and the word "Edinburgh," which must have become by frequent repetition, when he was well, thoroughly "well organised," were hopelessly mis-spelt. A facsimile representation of his signature, and of the word "Edinburgh" as he wrote it, are given in Fig. 20. He also made mistakes in writing individual letters. The letters "a," "o," "c," "g," "t," "p," and "e" were written correctly, but he wrote "w" for "v," and "v" for "b." On the same occasion he wrote "good" for "God," "goog" for "dog," "tct" for "cat," "alon" for "no," "htee" for "the," and "ndam" for "and." He also made mistakes in reading and writing figures and numbers. He was able to read and write single numbers (from 1 to 9) correctly; beyond this he was invariably wrong; the mistakes were in many cases repeated, although they were not in all cases identically the same. On different occasions he wrote the number 10 as follows: 100, 101. 1001. 10001, and 10101. On May 8th 11, 12, 13, 14, 15, 16, and 17 were written 111, 121, 131, 141, 151, 161, and 171. On June 2nd 14 was written 1141 and 15 was written 501. The number 100 was written on different occasions as 1001, 10001, and 100001. The number 20 was written on different occasions as 120, 210, 200; the latter mistake was made on two separate days. On one occasion 30 was written 300 and 310, 50 was written 1601, 60 was written 115, 70 was written 071, and 80 was written 8100. On June 2nd the number 10 was read as 100; 101 as 10; 1001, which he had previously written as 10 or 100, was not read, but he said, "Oh, it is millions." 201 was read as 300, and before arriving at this result he said: "That is a two and a one, that is three, that is three hundred." 20 was read as 200, 210 was read as 400, 150 was read as 155, 21 was read as 12, and 13 as 31. On June 8th 10 was read as 100, 1000 as 110, 101 as 111, and 1001 as 111. On the same occasion all the single numbers were read correctly. He was then asked to read 15, and said: "Oh, but you are coming it too heavy on me now." When pressed to try to read it he said: "That is one and five, that is six." In all these mistakes there is, it will be observed, the tendency to put in too many figures and to end up with the figure 1. Some of the mistakes, such as 210 being read 400, it seems impossible to account for.

FIG. 20.

Facsimile of the patient's signature and of the word "Edinburgh" as he wrote it on June 2nd, 1887.

(To be continued.)

A CASE OF PERSISTENT PRIAPISM.

BY ARTHUR H. WARD, F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS, LONDON LOCK HOSPITAL.

A MAN, aged thirty-two years, unmarried, applied for relief at the London Lock Hospital on April 20th, 1896. He had suffered from continuous erection of the penis with much pain for five days, and had had no sleep. On admission his family history was negative. He had had no illness or serious accident, had always been temperate, and had never lived abroad or suffered from ague. There was no history of any venereal disease. He stated that he always bruised very easily. Eight days before admission he had had intercourse, but had noticed nothing unusual afterwards. Five days before admission he got up at midnight to pass urine, having been asleep for some hours. On returning to bed erection of the penis occurred. This condition remained through the night unchanged, with much pain referred to the body of the organ. He went to work the next day, but afterwards remained in bed on his back with the knees drawn up. Any attempt to turn on his side was followed by greatly increased pain. There were no emissions or sexual desires. The patient was a small, weedy individual, with a weary aspect. The penis was hyper-erected, being almost in contact with the median line of the abdomen. The erection was confined to the corpora cavernosa, the rounded ends of which could be clearly felt through the substance of the glans, which, together with the corpus spongiosum, was perfectly flaccid. The corpora cavernosa were of almost wooden hardness, and fluctuation could not be felt. Any attempt to depress the organ caused acute pain; the skin was normal, and there was no localised swelling. The pulse and temperature were normal, the tongue was clean, and the urine was acid, with no albumin. The heart and lungs were healthy. The left side of the abdomen was somewhat rigid, and felt uniformly hard. The spleen was considerably enlarged, and its anterior margin could be felt near the umbilicus; no bruit or friction fremitus were present. The liver was apparently normal. There were large, soft, smooth glands in the groins, axillæ, and sides of the neck; they were moveable, painless, and discrete; the skin over them was natural. There were no signs of local hæmorrhage. The patient was not markedly anæmic, and complained of no symptoms of that condition. There was much pain and straining on micturition, so a soft catheter was passed periodically. The penis was treated with lead and opium lotion and supported by masses of cotton wool and a light bandage round the body. The bowels were opened with salines and citrate of potash and hyoscyamus given. He slept badly and required hypnotics. On the third day there was little change. An inflammatory swelling was found over the right corpus cavernosum near the crus, this subsided spontaneously. Iodide of potassium was given in ten-grain doses three times a day. The penis became very gradually less painful and rigid, and about the seventh day fluctuation could be felt over the corpora cavernosa. The spleen increased in size and the notch could be felt at the umbilicus, while the lower border extended down to the crest of the ilium. On the tenth day the Clinical Research Association reported on the blood as follows:—"Hæmoglobin and red corpuscles 50 per cent. of normal. Proportion of white corpuscles to red 1:8." Increasing doses of arsenic were given together with iodide of potassium. On the eighteenth day the patient could pass water without the catheter. The spleen was still increasing. The Clinical Research Association again reported as follows:—"In the specimen of blood examined the leucocytes are in greatly increased number in an average field—1:2. They are mostly of the large and not very sharply staining variety, but the eosinophile and granule cells are also increased. The lymphocytes do not seem to be increased. Poikilocytosis is not marked, but nucleated red blood-corpuscles are occasionally met with. A few cells of

Hosted by Google

doubtful nature, containing large splotches of material staining purple with methylene blue and eosine, are met with; these possibly are fragments of broken-down red blood-corpuscles. The blood is typically leucocythæmic and would point to the splenic variety of the disease." By the end of the fourth week the priapism was much less, and the penis fell forwards when the man stood up. He felt better in all respects and slept well without drugs. His condition continued to improve, and by the end of the eighth week the penis was almost normal. One or two indurated masses remained in the crura. On the morning before leaving the hospital the patient had a normal erection without pain which soon subsided. He was transferred to St. Mary's Hospital for further medical treatment. Two months later Dr. John F. H. Broadbent kindly reported that there had been no return of the priapism, that the spleen was very much smaller, and the condition of the blood improved. The patient had gained weight and seemed to be fairly well. The arsenic treatment had been pursued.

Remarks.—This rare case I consider to be one of spontaneous thrombosis of the corpora cavernosa consequent on the blood condition and established by an ordinary erection. The extraordinary hardness of the parts at first could only have been produced by the distension of the cavernous tissue with a passive clot. This large mass would naturally disintegrate in a few days and then afford a sense of fluctuation, but the thrombosis of the emissary veins persisting would prevent any escape into the circulation and at the same time keep up the condition of erection. I regarded the inflammatory swelling on the right side as probably surrounding a blocked emissary vein. The indurated masses which were felt in the crura at the end of the case were probably portions of the thrombus, which had organised more or less completely. The iodide treatment was adopted with a view of promoting the absorption of the clots, and this process was probably assisted by the local pressure, which at the same time gave the patient considerable ease by preventing the extreme tension which any displacement of the penis caused. I determined to avoid making any incisions if possible, although no doubt the disintegrated clots might have been squeezed out through them. But sepsis in this situation was only too likely to occur, and in the patient's general condition might have been disastrous. I doubt if anything short of actual suppuration justifies incisions in such a case, since even if sepsis be avoided adhesions between the trabeculæ must occur at the seat of the incisions and might cause distortion, while a septic condition would probably result in the entire loss of erectile power. I cannot help concluding that all these cases of persistent and rigid priapism must be referred to a local thrombosis due either to abnormal coagulability of the blood or to injury with laceration of the cavernous tissue or emissary veins, in which case thrombosis would occur as in the distal ligature of an aneurysm. The fact that the corpus spongiosum is generally unaffected indicates most strongly that neither reflex nor cerebral nervous irritation can be the cause of this condition; besides, it is nearly inconceivable that priapism could be kept up for weeks or months without exhaustion of the nerve centres if it depended on their

Hosted by Google

action. An essentially mechanical cause has to be sought for locally, and thrombosis, due either to coagulation or laceration, seems to account for the matter satisfactorily.

I have to thank Mr. A. Shillitoe, registrar to the London Lock Hospital, for the careful notes of the above case. He has also looked up and arranged the twelve cases given in the accompanying table; these are interesting especially from the point of view of treatment. These cases, with that already described, give thirteen examples of prolonged priapism, not the result of any cerebro-spinal lesion. Three were complicated with splenic trouble. In only four is the condition stated to have followed on intercourse. In three the final result was impotence. In Case 3 the organ is said to have afterwards performed its double functions satisfactorily. In the other cases the impairment or otherwise of function is not remarked upon. In the *New York Medical Journal* for 1888 Mr. George Peabody said he had collected thirty-two cases of prolonged priapism, six of which were complicated with enlarged spleen and its results. Among the six are a case under the care of Dr. Klemme (Schmidt's "Jahrbücher," 1866); one under the care of Dr. Louquet (*Allgemeine Medicinische Central-Zeitung*, 1876); and one under the care of Dr. Matthias (*Berliner Klinische Wochenschrift*, 1879).

Hertford-street, Mayfair, W.

ACCIDENTS ATTENDING VACCINATION.

BY P. MURRAY BRAIDWOOD, M.D. EDIN.,
CONSULTING MEDICAL OFFICER TO THE WIRRAL HOSPITAL FOR SICK CHILDREN.

FROM a copy of the "Inquiry into the Causes and Effects of the Variolæ Vaccinæ" (third edition, 1801, p. 5) I learn from the discoverer of vaccination that when milkmen and milkmaids get infected by vaccinia their systems become affected, "the pulse is quickened; shiverings, succeeded by heat, general lassitude, and pains about the loins and limbs, with vomiting, come on. The head is painful, and the patient is now and then even affected with delirium." This graphic description would apply to an attack by any of the causes which induce constitutional disturbance. It is therefore of no wonder that vaccinia, even in the mild form of arm-to-arm vaccination, is occasionally attended and followed by accidents. Jenner always maintained febrile reaction to be "the only perfect proof of constitutional affection and absolutely essential to the perfection of the prophylaxis." Without it he considered a vaccination to have been "merely local and quite or nearly without value." Again, in animal vaccination, where the vaccine has been continuously transmitted through heifers without having ever been in contact with human blood, the vaccinia pursues a definite course, papulation appears at the end of the third or beginning of the fourth day, areolation commences at the latter end of the ninth or beginning of the tenth day, the formation of crust or scab being accomplished on the sixteenth or seventeenth day, and falling off spontaneously about the twenty-fifth day. In children vaccinated with humanised lymph the stages of vaccinia are of much shorter duration. The crust resulting from animal vaccinia approaches very nearly the size of the vesicle, is of a rich brown or dark mahogany colour, and when employed for vaccinating children shows great reluctance to affect the human system. In animal vaccination there is noticeable very decided febrile reaction coincident with the rise, development, and decline of the areola, and the disease results in an indelible cicatrix or scar of a peculiar and well-defined type. On the other hand, vaccinia induced by humanised lymph runs a rapid course, its vesicles are easily ruptured, the crust is of much smaller size than the vesicles, falls off early, and the cicatrix forms a comparatively imperfect mark. It is well, further, to bear in mind the bovine origin of vaccinia, its relationship to diseases in the lower animals, its epidemic character when spontaneously generated in the bovine economy, but not when introduced there by inoculation; its analogy to, but not fraternity with, human epidemic affections, and its inoculability both into the lower animals and into man.[1]

[1] The Morphology of Vaccine Lymph, by P. M. Braidwood, M.D. Edin., in the British and Foreign Medico-Chirurgical Review, January, 1873.

It is no uncommon occurrence for a child to be exposed to measles, varicella, &c., and at the same time to be vaccinated, so that he is under the influence of two contagia, and the result depends on which of the two contagia takes the lead. "If," says Dr. Seaton, "vaccination has been successfully performed during the incubation of measles, but the vesicles have not reached their mature or areolar stage by the time that the disease manifests itself, it will very frequently, if not usually, be found that they will not go through that stage until such time as the measles have subsided." Jenner gives a very interesting account of two sisters in whom scarlet fever manifested itself on the eighth day after vaccination. In one the vaccine vesicle remained at its maturity, but "there was a total suspension of areola till the scarlatina had retired from the constitution"; as soon as this occurred the areola advanced in the usual way. In the sister the symptoms indicative of scarlet fever came on severely for about twelve hours; then a rash showed itself upon the face and part of the neck, but in two or three hours suddenly disappeared, and the patient was free from every complaint; it was then observed that the vesicle had the usual areola, and this continued till the fourth day, when it subsided, and scarlet fever again appeared and went through its course with the common symptoms. Vaccination has been repeatedly seen running its course along with scarlet fever, or measles, or chicken-pox. In the case of concurrent variola and vaccinia, if both diseases obtained equal mastery of the system, each pursued its own course as far as the local phenomena were concerned, though even then the constitutional effects of the small-pox were often somewhat modified. If, however, the small-pox had got a distinct mastery of the system before the cow-pox it was unaffected by the latter; and the cow-pox did not exhibit its full local phenomena when the system was under the influence of the small-pox contagion. If, however, vaccinia precedes variola it modifies the latter, or altogether prevents its development. Comparative pathology often exemplifies this. Vaccine lymph produces vaccinia, and no disease but vaccinia. These remarks, preliminary to the subject matter proper of this paper, seem to me to be called for by the hazy knowledge of vaccination I have met with among young practitioners and from the manner of teaching it I have experienced.

As regards, now, some accidents which may attend this great earthly blessing (vaccination). In the first place, the vaccination may not "take"; that means that the infective matter (vaccine) applied to the scratched surface of the skin does not affect the system and does not produce the desired vesicles. This accident may be due to the lymph being rubbed off before it has been absorbed, and can be avoided with a little care. The lymph should be thoroughly dried on the surface of the skin before the vaccinated spots are covered. Or the vaccine may not be "active" owing to its being not quite fresh, and having been stored too long. It should be used as soon as possible after removal from the vaccinifer. Secondly, in the case of vaccination of adults it may not succeed because they had been successfully vaccinated in infancy, and again about the age of fifteen or later. Thirdly, it seems hard occasionally to account for vaccination not succeeding till, a few days later, the child or the adult develops some other form of fever. For example, after a child has been carefully and properly vaccinated the vesicles do not appear, but he shows the morbillar or scarlatinal rash, or develops pneumonia. Either of these diseases had first taken hold of his system and prevented the vaccine lymph from having its effect. It is most important to learn from those who bring children to be vaccinated that they are perfectly healthy and well, and have not recently been exposed to infection. Adults, too, should bear in mind that they ought to be quite well before being vaccinated.

I have already mentioned that vaccinia affects the body as other constitutional diseases do; hence it is needful to avoid colds or other accidents which may interfere with its running the natural course. Sometimes as the vaccinia abates the affected arm becomes very red, swollen, and painful, even down to the elbow, while there is sympathetic axillary lymphangitis. At its commencement this distressing condition can be relieved by painting the surface of the arm once or twice lightly with spirit of terebinth, avoiding, of course, the seat of vaccination. A saline aperient is also useful when the constitutional symptoms are severe. The amount and extent of the inflammation attending vaccination varies according to the constitution and to the state of health of the person or child. From the third or fourth day

Hosted by Google

after vaccination, when the vesicles begin to form, the vaccinated spots should be protected from abrasion by stitching some cotton-wool on the inside of the sleeve. Vaccination shields are in my experience very hurtful. As vaccinia finishes its course troubles often arise through the vaccinated spots not healing rapidly. Various circumstances account for this, the most important being that the crust is rubbed off during sleep. If, then, the vaccinated spots are not protected, not only are they liable to receive surrounding impurities, but may lead to auto-inoculation. In the out-patient department of hospitals such cases are frequently met with, and the infant's mother wrongly ascribes it to the vaccine. Such impetiginous eruptions are really due to ill-health and uncleanliness and may appear on any part of the body. A form of eczema often attacks infants' heads and likewise is ascribed to vaccinia without reason. After the vaccine has dried on the scarified spots the infant can have his usual bath, but on no account should moist applications be used over the vaccinated spots. It should be remembered, too, that the irritation of teething often accompanies vaccinia.

The principal causes of bad and unprotective vaccination are, however, ascribable to the operator—the use of lymph taken at too late a period in the course of the disease, vaccinating with lymph removed from vesicles themselves badly developed or imperfect in character, the employment of lymph too long preserved, the use of a rusty or dirty lancet, and the manner of operating so that no blood is drawn and the lymph does not reach the cutis vera. It should be borne in mind that lymph from an exhausted vesicle is imperfect in power. It is improper, too, to vaccinate with lymph removed from a vesicle after the areola has been fairly formed, and it is decidedly injurious to vaccinate with lymph which is undergoing suppurative deterioration. An occasional accident attending vaccination is erysipelas.

In order to vaccinate always successfully great attention should be paid to details, and it requires a very decided degree of technical skill, patience, and experience. This is the more important when heifer vaccine is coming into general use. Its action is stronger than that of humanised vaccine.

Trevenson, Aylesbury.

NOTES ON THE TREATMENT OF SEA-SICKNESS.

BY M. CHARTERIS, M.D. EDIN.,
PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS AT THE UNIVERSITY OF GLASGOW.

IN my winter lectures it has been my practice to speak of the climatic treatment of disease, and notably of the magic effect produced by sea voyages. I had also to point out that in many cases the patient's liability to sea-sickness prevented the full use of this the best of nature's tonics, and in order to show my students how this disadvantage may be removed I have drawn their attention to the preparation called chlorobrom, which, as I know from personal experience, in many cases cures, and in all cases alleviates, sea-sickness. From time to time reports on its efficacy are sent to me by old students who have had experience at sea, and I have now some fresh cases to communicate.

Six ship surgeons previously prone to sea-sickness, who during the last six months have, by following my directions, sailed to Calcutta and back without suffering the least inconvenience, report as follows.

Examples of prophylactic treatment. — (*a*) Dr. Dunlop writes on Jan. 13th, 1897:—"I am an indifferent sailor, and the prospect of a voyage to India in the capacity of a surgeon was marred by the thought that I would suffer from *mal de mer*. By following the directions given me as to a cholagogue, dietary, and dosage of chlorobrom, I suffered no ill effects from the voyage." (*b*) Dr. McLure, on Jan. 23rd, 1897, reported as follows:—"Ordinarily a poor sailor, by acting on your directions I was enabled to reach Calcutta without the slightest feeling of nausea, and although on the homeward voyage we had a very rough passage across the Bay of Biscay, I was equally free from any feeling akin to nausea or sickness." (*c*) Dr. McNaught, on Sept. 25th, 1896, wrote *inter alia:* "In my own case I had an opportunity of trying chlorobrom as a prophylactic remedy, and I feel sure it was the means on several occasions of warding off unpleasant attacks of sea-sickness." The others testify in a similar manner. (*d*) Dr. Allan gives the following account of a case of prophylactic treatment: "A lady who had always suffered from sickness when the surface of the waters was troubled, was treated as follows. Before sailing she took, according to my advice, a smart calomel purge; on retiring to her cabin in the evening she had one drachm of chlorobrom; next morning a light breakfast and then another drachm of chlorobrom. At noon—the steamer beginning to roll—she had three drachms, and I asked her to lie down for an hour or two; she did this. She at no time felt sick, and in the course of the afternoon she expressed her astonishment and gratitude at such unaccustomed immunity."

Examples of curative treatment. CASE 1.—A man was very sick one hour after putting to sea. He had just partaken of breakfast. After the stomach was cleared he had a glass of soda water. Five minutes afterwards he took twenty-five minims of spiritus chloroformi. The stomach being now soothed, he had two drachms of chlorobrom and one drachm every half hour for three doses. About noon he fell asleep and awoke at 4 P.M. He had one drachm of chlorobrom and also three grains of calomel. He felt thoroughly well, and at 6.30 P.M. he sat down to dinner and enjoyed a hearty meal. The same course was pursued later when he sickened in the monsoon, and a similar happy result was obtained.

CASE 2.—A man, who had been previously free from any symptom of sickness, complained of depression and what I called mental pain and nausea. After taking a dose of calomel he lay down, and half-an-hour afterwards he was given half an ounce of chlorobrom. Towards night he felt better. At 8 P.M. and at 9 P.M. he took one drachm, and at 10 P.M. two drachms of chlorobrom. Next morning he was up early and, as he expressed it, "as lively as a cricket." For the next three nights he had one drachm of chlorobrom. At no time had he any return of the symptoms.

These cases are almost picked at random and are illustrations of the efficacy of chlorobrom. I have no hesitation in saying that, if administered in a sensible and thorough manner, chlorobrom will effectively meet each and every symptom of the dreaded sickness. And I am glad to give my testimony of the success of a treatment which I learned within the walls of my University.

Glasgow.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF FOREIGN BODY IN A BRONCHUS.

BY T. LAUNCELOT ARCHER, M.R.C.S. ENG.

IN November, 1895, I was sent for to see a boy, aged nine years, who had been ailing for a few days, gradually getting worse. The temperature was 103° F., there was a rapid, full pulse, the expression was anxious, and he had a short spasmodic cough without expectoration. The lower lobe of the left lung was congested, but all the remainder of the lungs was clear. I saw the child daily for more than a week, during which time his temperature varied but little, the congestion did not clear up, and the cough was, if anything, worse, added to which there were violent retching and some diarrhœa. He also complained of great pain about the level of the ensiform cartilage on the left side. Eleven days after my first visit I received an urgent message saying that the child was choking. When I arrived he was pale and exhausted, but quiet. His mother said that he had had a violent fit of coughing, lasting for twenty minutes, followed by some blood-stained expectoration. On examining the sputa I found a piece of a nut of the size of a large bean, surrounded by blood-stained purulent matter and mucus of very offensive smell. The child passed a quiet night, coughing only three or four times, but expectorating purulent matter, and in the morning he was decidedly better; from that time he steadily improved to complete recovery.

Hosted by Google

On inquiry his mother said that a fortnight before I was first sent for he was eating some nuts when a piece "went the wrong way"; he choked and coughed for a time, but soon recovered himself, and she thought that he had got the offending morsel up, but from that time he had complained of pain in his chest and he had been a little unwell until I was sent for. I suppose that the nut found its way into one of the bronchial tubes which it closed up, causing the lung mischief and setting up some inflammation resulting in a small abscess, and so becoming loose was coughed up, as I have described, a month after the accident. The case is an unusual one, and as such I have thus briefly described it, thinking it may be of interest to other readers of THE LANCET.

Vincent-square, S.W.

A CASE OF POISONING BY OYSTERS.

BY EDWARD BUXTON, M.D., F.R.C.S. EDIN., D.P.H.

ON Nov. 24th, 1896, at 9.30 P.M., I was hastily called to a man whom I found in bed writhing in the most intensely agonising pain in the epigastric region. I immediately gave him a hypodermic injection of half a grain of morphinæ sulphas and one-seventy-fifth of a grain of atropinæ sulphas, and applied flannels wrung out of hot water and sprinkled with laudanum over the region of the pain. Before my arrival he had fortunately vomited freely several times. When in the course of an hour or so the pain slightly moderated, upon inquiry as to the supposed cause of the trouble, I learned from him that he had arranged to dine with a few friends in the city (Liverpool) and to commence with he had three oysters. He was perfectly well when he sat down to dinner, but had not swallowed the oysters more than two minutes before a feeling of discomfort, rapidly merging into more and more acute painfulness, was felt in the stomach. Not wishing to disappoint his friends, he endeavoured to mask his condition, and partook of a little soup. The pain continued to get worse, however, but he still tried to bear it, and waited until the next course was served. The agony he then suffered overpowered him, and he was compelled to leave the hotel, and by means of cabs and railway reached his home, some five miles out of the city, and went to bed, where, as I have mentioned, I found him in great pain with symptoms of collapse rapidly setting in. I remained a considerable time with him and used morphine freely. The pain became somewhat modified by the opium, but lasted all the first night and following day. On the second day the pain had left him, but he was exceedingly weak. I prescribed four-hourly doses of a mixture of three grains of subnitrate of bismuth, ten minims of solution of perchloride of mercury, B.P., and two minims of diluted hydrocyanic acid until the stomach could retain milk and soda water, and subsequently a little dry champagne. On the fifth day he was able to resume his duties, and his recovery was uninterrupted.

The interesting point in this case arises from the exceedingly short period that elapsed between the time of swallowing the oysters and the onset of toxic symptoms.

Waterloo, Liverpool.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL. — The forty-eighth annual meeting of the Wolverhampton and Staffordshire General Hospital was held in the Bell Medical and Surgical Library on March 9th. The report showed that 1859 in-patients were treated during the past year; there were also 12,195 out-patients, who made 42,879 attendances. The average cost of the in-patients was £3 9*s.* 8*d.* per patient and £50 4*s.* 4*d.* per bed occupied; the average stay in the hospital was twenty-three and three-quarter days. The total income for the past year was £8714 and the expenditure was £8461. At the meeting held a year previously attention was called to the necessity for renovating the operating theatre in order to adapt it to modern requirements, and it was now stated that the necessary alterations and re-furnishing were carried out under the superintendence of Mr. T. Vincent Jackson, the senior honorary surgeon, at a cost of £287 11*s.*, and that the theatre was re-opened on July 24th last by Mr. Christopher Heath. In the afternoon a reception was held in the hospital and grounds by Mrs. Thorneycroft and Mrs. Twentyman.

ST. MARY'S HOSPITAL.

PERFORATION OF THE STOMACH BY CHRONIC ULCERATION; PERITONITIS; LAPAROTOMY AND SUTURE OF ULCER; RECOVERY.

(Under the care of Mr. A. QUARRY SILCOCK.)

OF the many morbid conditions at one time considered purely medical which have of late years been handed over to the surgeon, few give more satisfactory results from surgical treatment than perforation of a simple gastric ulcer; but it is essential that only a few hours should intervene between the perforation and the laparotomy, and the satisfactory ending of Mr. Silcock's case, though perforation had occurred twenty-four hours before operation, must be attributed to the careful cleansing of the peritoneum in the neighbourhood of the perforation. The method employed in this case to cover the perforation has been used for the treatment of dilated stomach, as in a case under the care of Dr. Ewart and Mr. Bennett.[1]

A woman, aged twenty-five years, was brought to St. Mary's Hospital by Mr. E. Archer Wood, of Dulwich, on July 11th, 1896, suffering from perforating gastric ulcer and peritonitis. Her history was as follows. She had been in delicate health since the age of sixteen years. On Sept. 5th, 1895, she suffered from hæmorrhage from the stomach and much vomiting. Since that date she had been under treatment for gastric ulcer from time to time, having once been an in-patient at Charing Cross Hospital. On the evening of July 10th, 1896, at 11 o'clock, whilst out for a walk, she was suddenly seized with pain in the left hypochondriac region, vomiting, and collapse. She was seen and attended immediately by Mr. Archer Wood, who diagnosed perforation of a gastric ulcer and prescribed such treatment as was possible under the circumstances; he prohibited any food or fluid by the stomach, and accompanied her on her journey to St. Mary's Hospital the next day. When seen by Mr. Silcock on the evening of the 11th, nearly twenty-four hours after the accident, she was evidently extremely ill and very pallid. The pulse was 100 per minute, regular, and fairly strong. Her temperature was 100°F. The tongue was somewhat dry. The respiration was entirely thoracic, 20 per minute; the diaphragm did not descend in inspiration; the abdomen was considerably distended, the distension being evenly distributed. She complained of pain and tenderness all over the abdomen, but especially in the left hypochondriac region. On percussion the abdomen was found to be generally tympanitic. The liver dulness was lost. The urine was normal. She was at once taken to the operating theatre. An incision about four inches long was made, commencing one inch to the outside of the ensiform cartilage and carried outwards on the left side parallel to, and about half an inch below, the lower border of the ribs. On the peritoneum being opened a large amount of gas escaped. The wound was found to be immediately over the perforation of a large gastric ulcer, through which white curds of milk mixed with gastric juice were escaping. The perforation was in the anterior wall of the stomach about two inches to the left of the middle line. A stomach tube was passed down the œsophagus, about ten ounces of fluid containing a good deal of white curd were syphoned off, and the stomach was thoroughly washed out. Around the perforation the stomach wall was indurated and covered with lymph. The zone of induration extended through all the coats and for an area roughly three-quarters of an inch in width beyond the margin of the perforation, which was about the size of a No. 9 catheter. The silk sutures, inserted

[1] THE LANCET, July 4th, 1896, p. 8.

Hosted by Google

after the method of Lembert with a view to closing the perforation, tore out by reason of the want of flexibility and friability of the infiltrated tissues, only one holding. The stomach wall was therefore widely reduplicated, the folds being vertical and made outside the zone of leathery induration, so that the perforation was overlapped by them; their peritoneal surfaces were brought into contact and fixed by silk sutures. The peritoneum in the immediate neighbourhood of the incision was then thoroughly cleansed by sponges and irrigation so far as was possible. The parietal wound was closed by sutures, except for a short distance over the site of the ulcer; the sutures passed thorough the entire abdominal wall, including the peritoneum and the integument. A gauze tampon was left in the open part of the wound for drainage. Dressings of cyanide gauze and wool were used. She was treated by nutrient enemata until July 22nd, when small quantities of liquid food were given by the mouth at frequent intervals. The recovery was uninterrupted, except that the wound suppurated, some fever being thus engendered in the earlier days after the operation, and she was discharged from the hospital on Aug. 29th.

Remarks by Mr. SILCOCK.—Two points in connexion with this case are worthy of note. In the first place, a considerable extravasation of the contents of the stomach into the peritoneal cavity had occurred during the somewhat lengthened interval between the time of actual perforation—as indicated by the sudden supervention of pain and collapse—and that of the operation; in that interval, quite contrary to the emphatic and reiterated orders of Mr. Wood, it was evident that the sympathising friends had induced or allowed the patient to ingest a quantity of milk. Indeed, so considerable was the amount of the contents of the stomach found in the neighbourhood of the perforation, and so marked was the peritonitis, that the chances of recovery seemed at the time of the operation to be but slight. Another point is the success which followed the manœuvre of making wide folds of the stomach wall so as to cover the perforation. It will be remembered that a somewhat similar proceeding has been recommended and adopted in America in cases of dilatation of the stomach with a view of lessening its cavity. One feared lest by some sudden strain, as by vomiting or coughing, the frail hold which the sutures had on the wide duplicatures might give way, and in any case the strain upon them must have been considerable, but fortunately there was no sickness after the operation. The use of the gauze tampons, now a favourite device with surgeons in similar cases, no doubt played its part in securing adequate drainage. The patient was last seen at the end of November, and had married. She would not be dissuaded from taking this step, although warned that the consequences might be serious; she was carefully carrying out the directions of Mr. Wood as to diet, and did not suffer from any pain after food; in fact, she was practically well.

Medical Societies.

HUNTERIAN SOCIETY.

Exhibition of Cases.

A CLINICAL meeting of this society was held at the London Institution on April 14th, Dr. G. E. HERMAN, President, being in the chair.

Dr. BUTLER HARRIS gave a demonstration of the Treatment of Chronic Ulcers by Ozone.—Dr. F. J. SMITH remarked on the probable usefulness of ozone in chest disease.—Dr. HARRIS pointed out that it would be too irritating.

Dr. J. H. SEQUEIRA showed a case of Infantile Hemiplegia in a girl, aged three and a half years, which followed after a fit; the paralysis involved the left side. He referred to two other cases; in all three recovery had taken place except in the arm affected. A distinction was drawn between cases of a congenital nature and those following a febrile attack.

Dr. F. J. SMITH showed a case of Spastic Paraplegia in a child aged five years. She had always been healthy except for the condition of the legs, in which there were increase of knee-jerks and ankle-clonus.—Remarks were made by Mr. A. H. TUBBY and Dr. ST. CLAIR SHADWELL.

Dr. J. F. WOODS showed two cases of Trigeminal Neuralgia successfully treated after three or four sittings by Hypnotism and Suggestion. Both these cases had been operated on previously by Mr. Charters Symonds, who had removed Meckel's ganglion in one case and had divided the infra-dental nerve in the second, and had attempted on another occasion to reach the third division of the foramen ovale without success. Both cases only temporarily improved and eventually relapsed into their former condition after surgical treatment.—Remarks were made by the PRESIDENT and Dr. GLOVER LYON.

Mr. HOPE GRANT showed a man who had suffered from Numbness in the Thumb, Forefinger, and Middle Finger of the Left Hand, with inability to flex them; sensation was diminished; he had had rheumatic pains for two years somewhat like "lightning pains." There were no loss of knee-jerks and no ankle-clonus; the pupils were insensitive to light, and there was no reaction to accommodation. The patient reeled when standing with his eyes shut. He had had a chancre in his youth and had been a hard drinker.—Remarks were made by Dr. GLOVER LYON, Mr. A. H. TUBBY, and Dr. F. J. SMITH.

Dr. GLOVER LYON showed a case of Fibrosis of the Left Lung with Paralysis of the Left Vocal Cord and with the left pupil smaller than the right.

MANCHESTER MEDICAL SOCIETY.

Peripheral Neuritis in Pregnancy and the Puerperium.—Notification of Phthisis.—Unusual Condition of the Spleen.

A MEETING of this society was held on April 7th, Dr. GRAHAM STEELL being in the chair.

Dr. ERNEST S. REYNOLDS gave a short communication on the forms of Peripheral Neuritis occurring in Pregnancy and the Puerperium. He separated those cases obviously due to injury or inflammation of the nerve roots in the pelvis from those of multiple neuritis affecting the arms or legs, or both, in which some poison was probably the cause. He pointed out how often in the latter cases there had been persistent vomiting of pregnancy, and related a case in which this had occurred.

Dr. JAMES NIVEN read a paper on the Notification of Phthisis,[1] in which he pointed out that with regard to the modes of transmission of tuberculosis and the means by which such transmission can be intercepted our knowledge is more complete than in the case of any other infectious disease. Notification of phthisis to be of much value must be compulsory. Difficulties will arise in connexion with the expense of notification; but the expense is not prohibitive. The class of cases which require notification comprises tuberculous phthisis, tuberculous diarrhœa, tuberculous glands and ulcers whatever may be the cause of the ulceration—in fact, all cases with well-marked discharge. In order to enable us to exercise some control over our public milk-supplies we also require notification of cases of tabes mesenterica. In connexion with the practical routine of notification it will be necessary (1) to make a careful record ledgered for names, addresses, and places of occupation of the cases reported—such a record will be of immense importance in tracing the pathways of infection; (2) to ascertain and remove the conditions which have proved active in producing the disease in the cases notified; (3) to see that strict personal hygiene is carried out for each case reported both in his own interest and that of others—this the medical attendant would be expected to see to, but information would be obtained by the delegates of the health office as to the steps actually taken; (4) to carry out disinfection and other arrangements for cleansing and for the maintenance of cleanliness in the surroundings of the tuberculous person, to disinfect rooms vacated by phthisical patients in hotels, lodging-houses, &c.; (5) to enable the medical staff of the health department to collect information and make investigations as to the conditions of propagation of tuberculosis with a view to prevention; (6) to enable education in preventive measures to be applied at the most useful time and in the most useful way; and (7) to assist the health officer in tracing tuberculous food infections.

Mr. C. E. RICHMOND showed a Spleen enclosed by a layer of very tough fibrous tissue which was two inches thick in

[1] This paper will shortly appear in our columns.—ED. L.

Hosted by Google

some places. This layer was apparently organised inflammatory deposit; it contained bloodvessels of considerable size and was outside the spleen capsule. The spleen pulp itself almost everywhere showed cirrhotic changes. The patient was a female aged twenty-eight years. There had been pain and gradual enlargement for two years, but there was no history of syphilis or ague. The condition of the blood and the clinical phenomena were not at all those of leucocythæmia. The other viscera generally were healthy.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Specimens.—Injury to the Brachial and Cervical Plexuses of Nerves.—A Case of Tetanus treated by Antitoxin; Recovery.—Lupus of the Vagina.—Twin Labour.—Vaginal Hysterectomy for Cancer.

A MEETING of this society was held on April 6th, the President, Mr. GODFREY CARTER, being in the chair.

Dr. EURICH gave a demonstration of Microscopical Specimens illustrating Locomotor Ataxy affecting the Cervical Region of the Cord, Ataxic Paraplegia, and Psammoma.

Dr. HOWARD GLADSTONE related two cases of old-standing Injury to the Brachial and Cervical Plexuses of Nerves, and described the appearances of the structures of the forearm as seen on dissection of the limb after amputation.

Dr. CHAPMAN related a case of Tetanus treated by Antitoxin and resulting in recovery. The patient was a man, aged twenty-seven years, who sustained a lacerated wound of the forearm. Tetanic symptoms commenced after a lapse of eighteen days; the wound had not suppurated freely, but there were some redness and gaping of its edges. The temperature was 100° F. The spasms were of moderate severity, but the patient was scarcely ever free from some spasm; they continued for eleven days, during which time 360 grains of antitoxin were administered subcutaneously. On the fourth day a macular rash appeared on the sides of the chest wall. One week after admission the patient became delirious and remained so for a fortnight. About the time that the administration of antitoxin was stopped pain and tenderness of several joints were noticed, and these symptoms persisted for some three weeks, although during the greater part of this time there was no febrile disturbance. Dr. Chapman said that the part played by the antitoxin in the successful issue of the case was somewhat doubtful, as from the first the prognosis was favourable, owing to the considerable lapse of time (eighteen days) between the receipt of the injury and the onset of tetanic symptoms.—Dr. CAMPBELL, Dr. HORROCKS, and Dr. SHIACH discussed the case.

Dr. HORROCKS showed a specimen of Lupus of the Vagina and made some comments on ulceration affecting the orifice of that canal. He said that there was a group of symptoms—namely, local smarting and aching pain, much increased by micturition, defecation, and coitus—associated with a condition of injection with superficial ulceration of the mucous membrane of the vulva, together with a whitish discharge. He further affirmed that these symptoms were not relieved by simple local treatment such as vaginal injection and emollient applications, or even by scraping the ulcers and applying caustic, as in the treatment of lupus, but that the only successful treatment was by free and deep excision of the ulcers, which had been followed by cure in a number of cases. Dr. Horrocks called attention to another condition of the parts associated with symptoms suggesting caruncle of the urethra. On examination there is found, instead of the vascular papilloma (caruncle) a mass of exuberant granulations blocking the urethral orifice and having the colour of lupus; these may spread on to the vestibule or along the floor of the urethra to the opening of the bladder, and may cause incontinence of urine. The ulceration spreads very slowly, but is very resistant to all treatment. This condition may be associated with the shallow ulceration of the vulva previously described. Dr. Horrocks pointed out that the confusion of true caruncle with this lupoid condition of the urethral orifice has led to the idea that caruncles may recur after removal.

Mr. HEBBLETHWAITE related a case of Twin Labour in which unusual difficulties occurred.

Dr. RABAGLIATI described three cases of Vaginal Hysterectomy for Cancer by Martin's method. The results were immediately successful, but in two of the cases recurrence of the disease took place after two and eight months respectively.

Dr. ARNOLD EVANS showed specimens of Measly Pork, and demonstrated the cysticercus of the tænia solium under the microscope.

Reviews and Notices of Books.

The Pathology and Surgical Treatment of Tumours. By N. SENN, M.D., Ph.D., LL.D., Professor of Practice of Surgery and Clinical Surgery, Rush Medical College, Professor of Surgery, Chicago Polyclinic, &c. Illustrated by 515 Engravings, including Coloured Plates. Philadelphia: W. B. Saunders. Pp. 709. Price $6.

THE name and work of Professor Senn of Chicago are so well known in England that the appearance of a treatise by his hand on so important a surgical subject as tumours must awaken general interest.

The volume naturally resolves itself into two parts: a portion dealing with the pathology of tumours, and a portion which is concerned with their treatment, though in the work itself the two divisions of the subject are mingled together, as the description of each variety of tumour is followed by an account of the appropriate treatment.

The first question which presents itself in the pathology is naturally, "What is a tumour?" The author, in answer, emphatically lays down the proposition that "a tumour is a localised increase of tissue, the product of tissue-proliferation of embryonic cells of congenital or post-natal origin, produced independently of microbic causes." This is practically Cohnheim's theory, with the not unimportant modification that the embryonic cells may be of post-natal origin, "being derived from pre-existing mature tissue in consequence of injury or disease, and failing to undergo the normal transformation may give rise to tumour formation in the same manner as embryonic cells of fœtal origin." The same idea is re-stated as follows: "We regard the matrix of embryonic cells as the essential cause of tumour-formation, without which all intrinsic and external exciting causes are inadequate to produce a true tumour." Cohnheim's theory of the "embryonic" origin of tumours was at one time very generally accepted, partly because of the extremely simple way in which it explained the existence of various forms of tumours, and partly because no other theory of any value could be advanced; but, except in the teratomata, the support which this theory receives from ascertained facts is very slight, certainly not more than sufficient to justify it being considered a very ingenious hypothesis, capable of explaining in a fairly satisfactory manner the occurrence of some tumours, and therefore it must be decidedly misleading to a student to have the theory, ingenious though it may be, stated as a fully ascertained fact. Dr. Senn further holds that to obtain a tumour of any special variety of tissue it is necessary that the "embryonic matrix" should be composed of embryonic cells identically the same and not merely derived from the same blastodermic layer. Thus we are told that "heterotopic chondroma" must have arisen from "a matrix composed of embryonic cartilage cells." The theory certainly seems to require a rather reckless scattering throughout the body of useless embryonic cells. There is another part of Professor Senn's definition from which we must dissent. In one of the passages already quoted we are told that a tumour is "produced independently of microbic cause." We practically agree with him when he says that "the microbic origin of tumours ..... has not been established by any convincing experimental investigations or clinical observations," though there are not wanting facts that are most easily explicable on this supposition; but Dr. Senn goes on to say: "Should

Hosted by Google

future research demonstrate a direct causative relationship between certain yet unknown bacteria and the growth of some of the tumours, such tumours would have to be eliminated from this group of pathological products and classified with the granulomata." That is to say, if carcinomata should ever be shown to be due to a micro-organism, then a scirrhus of the breast would no longer be a tumour. This is surely a *reductio ad absurdum*. Dr. Senn does not seem to recognise that, hough it may be convenient to try to obtain a pathological definition of a tumour which will embrace all those "swellings" which are usually classed as tumours, yet the word is generally and most conveniently used in a *clinical* sense. Certainly in the definition no etiological element should be introduced while we are still absolutely ignorant of the exact cause of any tumour whatsoever.

The pathological anatomy of the various growths is well described, and the clinical characters are excellently given. Numberless illustrations accompany the descriptions of the structure of the tumours; many of them are original, and some are admirably reproduced in colours. The classification adopted is simple, depending primarily on the blastodermic origin of the tissue in which the tumour appears.

Though we can speak very favourably of the pathological section of the work, yet, bearing in mind the author's reputation as a surgeon, we turn with the most interest to the clinical portion of the volume. A chapter is devoted to the general principles of the treatment of new growths, and here we find laid down careful rules for the palliative and curative treatment, with a description of the various methods which have been employed at different times. As we have already mentioned, the pathological description of each tumour is followed by its treatment, and in this way descriptions of a large proportion of the operations of surgery are given; for instance, we find an account of hysterectomy in the section evoted to the treatment of carcinoma of the uterus, and of nephrectomy for the same disease in the kidney; the operation of gastrostomy is described in the account of the treatment of malignant stenosis of the œsophagus, and rhinoplasty is given with carcinoma of the nose. Naturally the result is that the volume is large, but its excellence prevents it from being too large. The paper and printing are perfect. We must confess that we think the index might easily have been fuller, for it at present contains no reference to many of the subjects of which the book treats. The volume is inscribed to the memory of Samuel David Gross, and we can give no higher praise than to say it is worthy of such a dedication.

JOURNALS AND REVIEWS.

The Practitioner.—The most interesting paper in the April number of this journal is one by Mr. Watson Cheyne upon the Prophylactic Injection of Anti-streptococcic Serum. Mr. Cheyne has tried this method in three cases of removal of malignant disease about the tongue and the upper part of the pharynx; two of the patients recovered without any of the septic troubles which are so wont to follow such operations, the third died from a cerebral embolus washed into the brain from the lingual artery, and in this case there was a slight amount of sloughing. This method of protection certainly seems to promise well. Dr. Walter Smith reports an interesting case of Fœtid Suppurative Pericarditis. The Hero of Medicine for the month is Sir Charles Bell.

Quarterly Medical Journal for Yorkshire and Adjoining Counties.—The opening article is a clinical lecture on Differential Diagnosis, delivered by Dr. W. R. Gowers; the patient suffered from weakness of the legs with excessive knee-jerks and an affection of speech. Dr. G. Sims Woodhead describes the effect of a temperature of 50° or 60° C. in modifying the pathogenic activity of tubercle bacilli contained in tuberculous milk. He looks forward to the time when a saprophytic tubercle bacillus may be demonstrated which, though non-virulent in itself, may be the means of continuing the life of the tuberculous virus outside the body for very long periods. Mr. H. Lockwood (Sheffield) gives an account of a case of Myositis Ossificans in a boy aged four and a half years.

Edinburgh Medical Journal.—Dr. J. Batty Tuke contributes the first instalment of a paper on Clinical Cases illustrative of the Insanities. The brain of one of the patients, who died on the seventh day from acute mania, yielded cultivations of a bacillus of uncertain classification, which, however, had no pathogenic effect on guinea-pigs or rabbits. Dr. Tuke refers to various observers who have found micro-organisms in the brain or cerebro-spinal fluid of the delirious or insane. Dr. W. P. Herringham (London) describes a case of Paroxysmal Tachycardia, and gives a summary of fifty-three recorded cases. Dr. A. Francis Dixon (Dublin) writes on the Course of the Taste Fibres. He criticises the view held by Dr. W. R. Gowers that the fifth nerve is the nerve of taste, and concludes that taste impulses reach the brain by the seventh and ninth nerves.

Dublin Journal of Medical Science.—Mr. W. I. Wheeler gives a summarised account of sixty-one cases in which he either partially or completely excised the tongue. Several of these patients, operated on for cancerous disease, had no return of it afterwards for periods varying from one to fifteen years. Dr. Montague L. Griffin describes a case of enormous enlargement of the spleen unattended by leukæmia. The patient measured fifty-five inches round the waist. After twenty-one months' treatment with liquor arsenicalis the splenic area of dulness became normal and the patient regained good health.

Treatment.—The first two numbers of this new journal of practical medicine and surgery contain a variety of interesting original articles by writers each of whom is an authority on the subject of which he treats. The first paper in the first number is by Dr. James Taylor and fully describes the Management of Cases of Acute Myelitis. The patient should lie on a water-bed and every precaution should be taken to prevent the formation of bed-sores; constipation may often be diminished by belladonna extract; any form of counter-irritation is inadmissible until there is no further danger of the inflammation extending, but when this stage is reached the Paquelin cautery may be cautiously applied to the back. Dr. G. A. Sutherland writes on the Use of Chloral Hydrate in Some Diseases of Children; in his hands it has proved very useful in epilepsy, progressive chorea, and asthma. The articles in the second number include a good one by Dr. J. W. Silk on the Preparatory Treatment of Patients subjected to Anæsthesia. The editorial notes and comments, reviews of books, and abstracts from current literature supply a large amount of valuable information in a very convenient form. The price of the journal is 6*d*., and it is published on the second and fourth Thursday in each month by the Rebman Publishing Company, 11, Adam-street, Strand.

The *Veterinary Journal* for this month contains Notes on the Roorkhee Disease by Veterinary-Captain H. J. W. Mann, a disease in which innumerable filariæ are demonstrated, filariæ which in appearance are said to resemble somewhat closely the parasites found in surra, but which differ from these organisms in that they do not attack the red blood corpuscles, but appear rather to confine their attention to the liquor sanguinis. Eight Cases of Tetanus in the Horse treated with the aid of Behring's Tetanus Antitoxin are here recorded, the record being taken from the *Deutsche Thierärztliche Wochenschrift*, from which it is argued that Behring's antitoxin when administered at the proper time and in sufficiently large amounts (in some cases amounts measured in litres) can cure tetanus in the horse. The results obtained differ materially from those recorded by Nocard, but the

Hosted by Google

author, Veterinary-Surgeon Casper, maintains that these differences are accounted for almost entirely by the greater potency of the serum supplied by Behring with which he was able to work. (We should also add the enormous doses that could be used.) He says that "differences in results must accordingly be sought in the difference in effective value of the antitoxin employed, and there will be no difficulty in tracing them." Accounts of clinical cases and the "Order" of the Board of Agriculture as regards the muzzling of dogs are also given, whilst the veterinary profession are warned that another serious outbreak of pleuro-pneumonia has occurred in England. The Experimental and Clinical Study of the Aspergillus Fumigatus is continued, and a number of other papers and abstracts, notes and news, and reports of veterinary associations are also given.

The *Veterinarian* for April contains several interesting original articles, the first of which, by Veterinary-Captain R. W. Burke, is a note on Malarial Fever or "Surra" in Horses in India, a disease very similar to the tsetse-fly disease of South Africa. An interesting parallel between the organisms found in malarial fever in man and those met with in the blood of horses is drawn, though the author does not adduce sufficient evidence to prove that the diseases are identical or are caused by the same parasite. Mr. A. E. Mettam contributes an account of a case of Cyclopia in the Sheep. In this number there is also an article by the late Professor Walley, Principal of the Royal Dick Veterinary College, Edinburgh, on the Prevention and Suppression of Contagious Diseases of Animals, the last important paper written by him. He draws a distinction between contagious diseases, infectious diseases, and those which are both contagious and infectious. In the first group are included in the present part of the paper "specific urethritis" and "rabies," two diseases which he maintains are purely contagious or infectious only in a limited degree. The Month's Progress and some interesting notes on Current Topics will be read with interest by members of both the veterinary and medical professions. The reports of the various veterinary societies are also of considerable interest.

In the *Phonographic Record* for April Dr. Gowers, after narrating a Case of Hæmoptysis accepted for Insurance as a Loaded Life, lays down the principle that recurring hæmorrhage from the lungs, however slight, should preclude insurance. Mr. Lamming Burton concludes his interesting Notes on the Life of a Ship Surgeon, and says that for pleasure, for health, and possibly for the experience to be gained, the life is to be recommended; but the man who takes a ship in the hope of making money or reading for an examination will find he has made a mistake. The life grows on a man, making it more and more difficult for him to settle down to the humdrum routine of general practice; unless he is a teetotaler and on a good line he will be out of pocket, and the life in time has a lowering tendency, so that a man's sympathies are blunted. But for teaching self-reliance and confidence in one's self the life is an excellent monitor. A ship surgeon should unite a trinity of virtues in a unity of body, and should be a medical man, a sailor, and a card-player. If he can sing or play some musical instrument and has a stock of novels he will be all the more popular. Mr. Peyton Beale writes upon Flat-foot and its Treatment, whilst a short account is given of the efforts which the Society of Medical Phonographers has made to render the inclusion of shorthand in the medical preliminary examination practically effective.

Scottish Medical and Surgical Journal.—Professor D. J. Hamilton (Aberdeen) criticises the view that pulmonary hæmorrhagic infarction (pulmonary apoplexy) is due to embolism, and argues that it is caused by blood from ruptured capillaries injecting a group of air vesicles and their attendant bronchus. Dr. G. T. Beatson (Glasgow) discusses the Value of Cachexia in the Diagnosis of Malignant Disease, and describes a case in which well-marked cancerous cachexia was associated, not with cancer, but with myoma of the uterus. Dr. T. G. Nasmyth gives details of the distribution of cancer in Scotland. Altogether there are nine original articles.

Mercy and Truth.—The mission hospitals described this month are those at Pakhoi and at Hangchow, both in China. There is an article stating that the committee of the Church Missionary Society feels that, as a general rule, it is better for a medical missionary not to be in holy orders.

The Journal of Pathology and Bacteriology. Edited by G. SIMS WOODHEAD, M.D. Edin. Vol. IV., No. III. March, 1897. Price 8*s.* 6*d.*—1. The Varieties of Ankylosis by Bone in different parts of the Skeleton, by Joseph Griffiths, in which the normal ankylosis which occurs between certain bones before birth or at different periods during life, as well as those due to pathological conditions, are fully considered and illustrated. 2. The Mechanism of Reaction to Peritoneal Infection, by Herbert E. Durham. In this paper the changes that take place in the peritoneal fluid are very clearly described, and Mr. Durham makes some suggestions as to the nomenclature of the cells found which will probably prove very useful. Part of this important research was recently communicated to the Royal Medical and Chirurgical Society, and reported in THE LANCET of March 13th, 1897. 3. The Toxins and Antitoxins of Symptomatic Anthrax, by William Hanna. 4. Resistant Forms of the Pneumococcus, by J. W. Eyre and J. W. Washbourn. 5. A Case of Fibrinuria in a Child, by David M. Greig. 6. Fibro-lipoma of the Kidney, by A. S. Warthin. 7. Keratinising Epithelial Tumour of the Scalp, by S. G. Shattock. 8. Formalin as a Preservative for Cultivations of Bacteria. By this method the growth of organisms on different media can be stopped at any period, characteristic appearances are preserved, and the specimens utilised for teaching purposes.

Australian Medical Gazette.—In the February number Mr. G. T. Hankins records a case in which, during the removal of a sarcoma from the left subclavian triangle, the thoracic duct was accidentally wounded. Mr. Hankins then divided the duct completely across and ligatured both ends. The patient made a good recovery, and has, so far, suffered no inconvenience and has gained 7½ lb. in weight. Dr. Sydney Jamieson describes three cases of beri-beri in Chinamen associated with jaundice, in which, post mortem, he found that the bile-ducts were dilated and filled with numbers of fluke (*distoma sinense*). The gall-bladder and common bile-duct contained no flukes. He ascribes the jaundice to the obstruction of the ducts by the flukes.

New Inventions.

THE STETHONOSCOPE.

WE have received from Messrs. Maw, Son, and Thompson, of Aldersgate-street, E.C., a specimen of the stethonoscope, an instrument constructed on the principle of the microphone, and intended to be attached to the ordinary binaural stethoscope, in order to magnify the sounds within the chest. It is stated to be of English manufacture, and it is claimed for it that "the variety of râles can be most easily distinguished, and areas of tubular breathing can be mapped out with greater facility than heretofore. ..... Murmurs can be distinguished which under other circumstances would pass unnoticed." The instrument certainly magnifies sound, but though there are fewer noises produced by creakings of the instrument itself than in the case of the phonendoscope, there are spontaneous noises which at first are very confusing. It does not appear to

Hosted by Google

magnify all sounds equally, and during a somewhat extended trial of the instrument we have found no instance in which any more information has been obtained about a case than had already been made out by the ordinary binaural stethoscope, except in the case of adults with much deposit of fat on the chest wall, in which the magnification of the sounds was of distinct advantage. The instrument is small and can quite well be carried about in the waistcoat pocket. A chest piece for the binaural stethoscope is supplied with the instrument. The price, in case, is 21*s.* 6*d.*

NEW SURGICAL NEEDLES.

MESSRS. MAYER AND MELTZER, of 71, Great Portland-street, have sent us a set of twelve newly designed surgical needles, which they have called Hagedorn's Reversed Needles. The first six figures of the illustration show the exact size and shape of the fully curved needles; the next

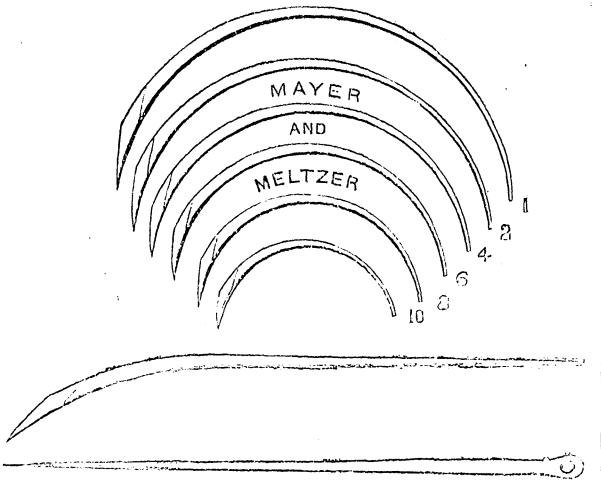

figure similarly represents the largest of the six needles of the straighter pattern. The advantage of Hagedorn's needle is claimed for this pattern in respect that the point is flat, but the eye being reversed, or, in other words, pierced not from side to side of the needle but from front to back, the needle can be held firmly with any ordinary holder, thus dispensing with the costly Hagedorn's needle-holder.

Analytical Records
FROM
THE LANCET LABORATORY.

SCHACHT'S NEW DIGESTIVE FLUIDS.
(GILES, SCHACHT, AND CO., 52, ROYAL YORK-CRESCENT, CLIFTON.)

SATISFACTORY combinations of the active digestive principle of malt with pepsin are the exception rather than the rule, and practitioners will accordingly welcome the introduction by Messrs. Giles, Schacht, and Co., of three excellent and reliable preparations of this order. We have thoroughly tested the "Schacht Bi-digestive Fluid," which is a combination of their "pepsina liquida" with a very active fluid malt. It proved to act powerfully, under proper conditions, both upon white of egg and starch, converting them into easily assimilated food substances. In addition it is by no means unpleasant to the taste. The "Schacht Bi-digestive Tonic" exhibits a similar excellent composition and degree of digestive activity, but contains also the bromo-hypophosphites of lime, iron, and potash, with cinchona and nux vomica. We had no difficulty in demonstrating the presence of each of the constituents thus enumerated; it should prove to be a reliable and valuable therapeutic combination. The third preparation, known as "Coca Bi-digestive," possesses again the active digestive properties of malt, diastase, and pepsin. It is suggested as possessing restorative and stimulant properties referable to the presence of coca extract, and is indicated in nervous depression as a useful digestive agent or in other debilitated conditions. We were easily able to separate the cocaine on suitable treatment with ether, the alkaloid being recognised by producing a marked numbing sensation when rubbed upon the tongue. The preparation, though sweet to the taste, is free from sugar and contains no alcohol. As aids to digestion, especially in enfeebled conditions, these preparations will be of undoubted service.

SOLIDIFIED SOUP SQUARES.
(E. LAZENBY AND SON, 18, TRINITY-STREET, S.E.)

We prepared some of these "squares" in the manner directed, and found them in each instance to yield a really good, palatable, and nutritious soup. The Julienne "square" consists of a cake of extract of meat enclosing a selection of desiccated vegetables, as carrot, onion, &c. The vegetable sections become softened on boiling, while at the same time they impart to the liquid a pleasant vegetable flavour. The tomato "square" consists of a uniform mixture of desiccated tomato soup, stock, and farinaceous substances. The resulting soup possessed the agreeable piquant taste of the fresh tomato. The thickness and starchiness might perhaps be reduced a little with advantage. The gravy "square" was evidently of the same composition as the Julienne "square," but without the addition of vegetables. The mulligatawny square proved to yield a rich, aromatic, but somewhat pungent soup made thick by a proportion of flour. The list includes also carrot, lentil, green pea, household, vermicelli, tapioca, and haricot "soup squares." Judging from those which we tried, which were taken at random, these preparations serve admirably as economical portable, and palatable nutrients.

HEALTH BATH SALT.
(CHARLES JUNE AND CO., 15, LOWER PHILLIMORE-PLACE, HIGH-STREET, KENSINGTON.)

This salt, according to our analysis, consists of a mixture of innocuous materials, chiefly bicarbonate of soda and borax, for use in the bath. It could be made more pleasant by the selection of more agreeable aromatic agents. It smells decidedly of turpentine, with a trace of orris root, which latter is more perceptible when the salt is dissolved in water. It may be used in the bath with advantage as contributing more effective detergent properties than when soap and water are alone employed.

(1) ESSENCE OF COFFEE; AND (2) COFFEE WITH CHICORY.
(PEEK BROTHERS, WINCH, AND CO., 20, EASTCHEAP, E.C.)

The genuineness of both these preparations is evidenced in the fact that we obtained a satisfactory yield of the stimulating principle, caffeine, on suitable treatment. The pleasant aromatic flavour of the freshly roasted berry is also preserved. In this respect the flavour of the coffee preparation unmixed with chicory is, we think, superior, although, of course, the latter possesses more body, and on that account may be preferred by not a few. Both preparations are as satisfactory as any we have previously examined, and an instructive comparison of the merits of various coffee extracts will be found in THE LANCET of July 7th, 1894.

ANTISEPTIC PELLETS.
(THE SANITAS COMPANY, LIMITED, BETHNAL-GREEN, E.)

The convenience of these pellets for the extemporaneous preparation of an antiseptic solution of definite strength is obvious. Thus one of the corrosive sublimate pellets, which are coloured blue when dissolved in half a pint of water, yields a solution containing one part of corrosive sublimate in 1000 parts of water. This constitutes the antiseptic solution prescribed by the Local Government Board. The permanganate of potash pellets contain five grains of the salt, so that

Hosted by Google

one dissolved in a pint of water gives a conveniently strong disinfectant solution; whilst one dissolved in one ounce of water yields approximately the liquor potassii permanganatis B.P. The carbolic acid pellets contain two grains of the acid, which, dissolved in half a pint of water, give a solution convenient for most purposes.

PERFECT HEALTH RUSKS.

(A. J. G. KING AND SON, 19, REGENT-STREET, SWINDON, WILTS.)

Special attention appears to have been given to the choice of ingredients in the preparation of these articles of food. Thus the milk used is sterilised, and a certain proportion of malt extract introduced. The rusks are acceptably crisp, and of a somewhat sweet flavour due to the malt sugar, and to the digestive effect of the diastase upon the carbohydrates. They contain a small proportion of branny particles; they are well made and afford a useful and convenient form of food.

EMULSIO OL. MORRHUÆ (HAYES).

(R. O. HAYES, HAYWARD'S HEATH, SUSSEX.)

The following formula is suggested to enable the quick preparation of a satisfactory emulsion and its administration when freshly made: sodium hypophosphite, 20 grains; liquor calcis saccharatus, 1 drachm; cinnamon water, 1 ounce; cod-liver oil, 1 ounce; and oil of cinnamon, 1 drop. The soda salt and lime syrup are placed in a three-ounce bottle with the proper quantity of water, and after solution has taken place the contents are transferred to a measure. Into the bottle thus emptied the cod-liver oil, to which one drop of cinnamon is added, is poured, and to this are added the hypophosphites and lime mixture in quantities of a drachm at a time, shaking well after each addition. In this way an excellent emulsion may be extemporised in a few minutes, and it keeps for a fairly long time without separation. We succeeded in obtaining a good emulsion by following these simple directions, a knowledge of which should prove useful to practitioners. The suggestion is said to be the outcome of considerable experience in the preparation of emulsions.

CARBOLIC LOZENGES.

(BLAKE, SANDFORD, AND BLAKE, 47, PICCADILLY.)

Lemon flavouring is employed in these lozenges to mask the taste of carbolic acid. It is a very successful combination, the disagreeable flavour of carbolic acid in the mouth being fairly well disguised. They afford a useful and convenient means of administering small doses of the acid as a local antiseptic.

BUBONIC PLAGUE IN BOMBAY.

ACCORDING to the weekly returns published on the 15th inst. there were 390 cases of plague, of which 194 proved fatal, in Bombay, against 360 cases and 323 deaths in the preceding week, and the mortality from all causes was 970, against 1007. It is estimated that the total number of cases of plague in Bombay since the outbreak of the epidemic amount to 11,333, of which 9493 were fatal. The official reports received by the Secretary of State from the Governor of Bombay contain pretty full information regarding the state and progress of the epidemic. The Governor states that, as regards Poona, satisfactory progress is being made in disinfection and sanitary work and in the diminution of mortality. The death-rate in the Mofussil, however, continues high. In Poona city for the week ending March 12th last, the deaths from plague and from all causes were 160 and 434 respectively; for the week ending April 9th they were 149 and 219, the normal weekly deaths being from 60 to 70.

"In the Mofussil districts the figures are:—Surat district, 310 cases, 220 deaths; Thana district, 369 cases, 323 deaths; Satara district, 1 case, 1 death; Ratnagiri district, 6 cases, 3 deaths; Kolaba district, 176 cases, 155 deaths; Poona district, 1 case, no death; Ahmedabad city, 1 case, 1 death; Kathiawar, 15 cases, 13 deaths; Cutch, 18 cases, 12 deaths; Baroda, 51 cases, 39 deaths; Palanpur, 23 cases, 19 deaths; Karachi city, for the week ended April 9th, 161 deaths. Search parties are at work; disinfection of clothing and bedding of all suspicious arrivals at Karachi is enforced. In Haidarabad and Sukkur number of plague deaths increased. Two-thirds of Sukkur is described as deserted and three-fourths of population said to have left. No signs yet that Rohri or Shikarpur is infected."

A long report from the *Times* correspondent at Simla on the 18th inst. is published in that journal of the 19th inst. It gives a description of the progress of the plague in Western India and Sind. The disease, which was at first described as bubonic fever, appeared in Bombay city early in October, 276 deaths being officially reported in that month. The deaths went on increasing during November, December, and January, and in February had reached 3072; there was a fall in March, and a still further fall during the first fifteen days of April, when they dropped to 804, showing a marked improvement. "The week of highest mortality was that ending on Feb. 9th, when the deaths from all causes in Bombay were 1891, or at the rate of nearly 120 per mille on the assumed population of the city, from which some 300,000 people had fled. This rate had sunk to under 71 per mille in the week ending March 30th, and it is now considerably lower owing to the practice among the native population of concealing cases. The official returns show only known deaths from the plague, whereas many thousands more must have occurred. Hence the true test of the decline of the disease is the falling off in the number of deaths from all causes. The returns recorded officially give 11,300 seizures with 9662 deaths in Bombay city from Oct. 2nd to April 15th. The percentage of recoveries was thus very small."

"In Karachi the plague broke out on Dec. 10th, 59 deaths occurring in that month. The mortality rose to 745 in January and 971 in February, and then sank to 868 in March, while 301 deaths have been reported in the first half of April, which goes to show that the disease is declining as in Bombay."

The plague in Karachi seems to have been of a severer and more fatal type than in Bombay, 2944 deaths having occurred out of 3531 cases.

The statement in the *Times* goes on to furnish figures and details of the epidemic in the areas outside Bombay and Karachi—in Thana, Poona, Surat, Colaba, Sukkur, and Haidarabad (Sind), and other places. The *Times* correspondent concludes his statement as follows: "To review the whole position, the area of which the plague has taken hold forms less than a tenth part of India. The disease shows no signs of spreading into the heart of the country, and it is reasonable to hope that it may gradually die out, as fewer cases are now reported from day to day."

The Governor of Bombay has been occupied in making some conciliatory and explanatory speeches at Poona and elsewhere regarding the aim and object of the Epidemic Diseases Act, and has given his assurance that the Government was doing everything in its power in the interest of the people to stay the plague. Great care will be taken to make proper arrangements for male and female patients and to protect the privacy of the latter by the employment of females to visit and attend upon them; also to feed the sick and to indemnify the owners of property that had to be destroyed. Of course, there have been various exhibitions of resentment and some rioting here and there on the part of the Mahommedan population, but the opposition to Government measures has so far been much less than might have been anticipated. We are glad to be able to congratulate Mr. Hankin on his recovery; his services generally in India have been very great, and he has not spared himself during the present epidemic; indeed, all have worked enthusiastically and well during the crisis which is, we trust, now subsiding.

NORTH-WEST LONDON HOSPITAL.—The annual meeting of the North-West London Hospital was held in the institution on April 6th, Lord Rathmore presiding. The report showed that during the year there were 578 in-patients under treatment; there were also 17,800 new out-patients, and 38,545 attendances. The total income for the year was £6863, including £1000 from Baroness de Hirsch, £1000 from Mr. Herring, £383 from the Hospital Sunday Fund, and £149 from the Hospital Saturday Fund.

THE LANCET.

LONDON: SATURDAY, APRIL 24, 1897.

THE enormous responsibility of the medical profession with regard to hospital abuse becomes more and more apparent the more closely we investigate and study the subject. The profession is used by hospital authorities for their own purpose and very much according to their own sweet will. If the out-patient rooms have to be enlarged, or if a little money has to be made by applying wards meant originally for the poor to the purposes of those who can pay, the members of the medical staff are expected to fall in with the views of the committee and to accommodate their services to the exigencies of the situation. And hitherto the profession has proved most acquiescent. There is scarcely an instance on record of emphatic protest and refusal to fall in with schemes which are ruining and demoralising medical practice. We make every allowance for the insidious and gradual growth of the system of indiscriminate hospital relief and for the kindly motives with which it has been associated in the minds of the promoters and in the minds of the members of the profession who have been its principal supporters. We remember the exigencies of medical education and all the arguments with which on this score such a system has been defended. But with all deductions and qualifications the fact remains that hospital practice is threatening private practice and that the public is being demoralised by indiscriminate medical charity in a way for which there is no excuse and which has no parallel in connexion with any other department of human wants; and we feel that for this state of matters the medical profession has largely itself to thank and to blame.

It is customary to speak as if the principal responsibility for this serious state of matters rested with the medical staffs of the hospitals. And undoubtedly this is true. Moreover, we ourselves have been foremost in pointing out that such is the fact, and at this critical juncture we look chiefly to them for the salvation of the profession from this huge evil. They are not selfish men. They are for the most part men of high education, proud of the traditions of the profession and of the old-fashioned charity which has created and maintained our voluntary hospitals for certain high purposes. They do not want to see these noble institutions converted into cheap dispensaries, demoralising those who come to them and sapping their self-respect and providence. Moreover, as medical teachers they have a real and natural interest in the success of the pupils they educate, and would not willingly compete with them in the less pretentious ranks of general practice. If they have done much harm we believe it to have been done unconsciously and unintentionally, and we are certain that when convinced of the fact they will be the first to demand reform in hospital administration and to vindicate the rights of private practice. By united action and representation they could reduce the scandal of hospital abuse in six months to half its proportions, and in twelve months they could practically abolish it altogether. They have the ear of the committees, executive and general, of the hospitals. They know the working of the evil system, and how, without much direct benefit to them, it threatens the very basis of private practice. Their intercourse with general practitioners must suffice to supply them with constant instances of men, whose education they have conducted and whose efficiency they know, being discouraged and dispirited in the battle of life, waged in neighbourhoods which cannot altogether do without them, but which the hospitals demoralise by gratuitous attendance or by a system of petty charges which convey the lowest suggestion of the value of medical service.

But while we think seriously of the way in which the honorary staffs of hospitals are responsible for hospital abuse we do not think that they are the only members of the profession who are to blame. General practitioners are themselves often parties to hospital abuse. For one reason or another they send patients, whom they know to be capable of paying private fees, to hospitals and often to particular members of hospital staffs. It may be to please the patient or to rid themselves of the trouble or responsibility of cases which they do not care personally to treat; it may be to humour the meanness of a patient who could pay but would rather not; but on some ground or other of a doubtful character they often suggest the hospital to patients who can afford to pay a reasonable fee for a private consultation. When the question comes to be investigated further this statement will be borne out, and the members of the medical staffs will be able to show that in cases of abuse they are often acting on the suggestions of private practitioners. It is in vain for general practitioners to complain of hospital abuse if they themselves are parties to it. No doubt a decent and respectable private patient, from the general practitioner's point of view, may often be incapable of paying the fees of a consultant whose opinion the practitioner desires. But ways of meeting this difficulty will be found when the different sections of the profession whose business it is to rectify present abuses come into friendly consultation for the purpose. We content ourselves here with saying that both consultants and general practitioners are to blame, and that they will be wise to confer with each other on the subject rather than indulge in mutual accusations. One thing is certain, that both consultants and general practitioners are serious sufferers from the existing state of things. Patients who can pay consulting fees and the fees of general practitioners are shown to be receiving gratuitous treatment in all our hospitals for comparatively slight diseases as well as for grave ones. For the sake of their common interests, as well as the interests of the public, both sections of the profession should consult together for the remedy of this grave abuse of charity.

THE annual summary of births, deaths, and causes of death in London and other great centres of population has at length been issued from the General Register Office. This publication, which relates to the year 1896, appears this

Hosted by Google

year even later than is usual. And inasmuch as the annual reports of the metropolitan medical officers of health cannot be completed until certain statistical information which the summary contains is available, it follows that the presentation of these important documents to the local authority is also delayed in consequence. We are led to make these remarks, not from a desire to find fault unnecessarily with a public department, but because we attach a high value to this particular publication of the statistical department of Somerset House. We candidly express our appreciation of the improvements which have been effected of late in the Registrar-General's annual summary and annual report, as well as in his weekly and quarterly returns; and it is to direct attention to a most important statistical development in the present summary that the following remarks have been penned. The information contained in the present issue differs in no appreciable degree from that presented in previous summaries so far as the thirty-two great towns outside the metropolis and the sixty-seven other large towns dealt with by the Registrar-General are concerned. It is in respect of London, and especially of its forty-four sanitary areas, that we notice the chief innovations in the summary for 1896.

We are told that the rates of mortality in the sanitary areas of the metropolis, when calculated on the deaths locally registered, convey very erroneous ideas of the relative healthiness of these areas. The presence of hospitals, workhouses, and other large public institutions in certain parts of London unduly raises the recorded death-rate of the areas in which they are situated, whilst the mortality of other areas from which patients have migrated to those institutions is correspondingly lowered. Until the deaths occurring in public institutions have been distributed to the sanitary areas from which the patients originally came no reliable rates of mortality for these areas can be calculated. For some years past the deaths occurring in metropolitan institutions have been distributed to the areas from which the patients were derived, but no attempt has been made to calculate rates of mortality in the absence of reliable data as to the population of these areas. In the present summary the actual rates of mortality from all causes, and from certain specified causes, are published for the first time, the inauguration of a quinquennial census for London in 1896 having rendered it practicable to form estimates of population from year to year which perhaps may be regarded as sufficiently accurate for this purpose Several tables are given showing the death-rates in the several metropolitan areas after due correction for institution mortality. In the case of phthisis, for example, some of the London sanitary areas afford striking testimony as to the necessity of distributing deaths occurring in public institutions in order to arrive at a fairly reliable measure of local mortality from that disease. Thus, for example, in Kensington, which area contains the Marylebone Infirmary and the Brompton Hospital for Consumption, 407 deaths were registered during the year 1896; but it was found on examination of the entries relating to these deaths that nearly half of them were of non-residents which had taken place in Kensington public institutions. After distribution of these deaths the Kensington death-rate from phthisis was reduced from 2·35 to 1·42 per 1000. St. Olave is another sanitary area similarly in point. This area contains Guy's Hospital, the deaths of non-residents occurring in which had the effect of raising the registered death-rate from phthisis of St. Olave by 3·04 per 1000 in excess of the true rate. On the other hand, St. Margaret Westminster, Clerkenwell, Limehouse, St. Saviour's, St. George Southwark, and Newington are examples of sanitary areas the death-rates from phthisis of which have been very considerably increased by the apportionment thereto of deaths from phthisis which had occurred in hospitals outside the boundaries of those areas.

An interesting table is inserted at page 7, in which the death-rates of the various sanitary areas of London are given (1) as registered and (2) after distribution of deaths in public institutions. Study of this table at once shows the effect of distribution in the case of London sanitary districts. Take, for instance, the case of Hampstead, which in 1896 had a registered death-rate from scarlet fever of 1 22 per 1000; correction reduced this rate to 0·09. The registered death-rate of the same district from diphtheria was 3·24, but when the deaths were distributed it fell to 0 39. On the other hand, the district of Chelsea had a recorded death-rate of 0·51 only from diphtheria; but when the hospital deaths were fully distributed the rate became 1·17. The effect of distribution is even more apparent in the case of mortality from phthisis, and the table referred to gives numerous instances of important alterations of the local death-rates attributable to this disease. In the year 1896 the net gain in life saved in London was represented by 6854 lives. In other words, had the average death-rate in 1886-95 continued throughout 1896, that number of lives would have been sacrificed in addition to those actually lost. In this year there was in London an excess of 938 deaths from measles, 797 from diphtheria, 256 from whooping-cough, and 483 from cancer. Under most of the headings the mortality in 1896 was below the average.

THE subject of premature burial has recently been discussed in Paris, and although the result has not brought the contending parties to general agreement on the value of the signs of death, it has served the purpose of showing that there is still much to be desired in the verification and certification of that event. In the large towns in France there exists a system which would, if properly carried out, afford a satisfactory safeguard against "live burial." Two certificates of death are required, firstly, by the medical attendant, and, secondly, by the official verifier. But Dr. OSCAR JENNINGS has shown that the latter too often performs his duty in a perfunctory manner, instead of satisfying himself of the fact of death by strict personal observation. Thus far the fault lies not with the legislature but with the executive, but there are said to be out of 36,000 communes (parishes) in France 29,000 without any medical practitioner, and consequently in such there is no medical certification. It is against Sir HENRY THOMPSON'S eulogy of the French system that Dr. JENNINGS brings these damaging statements. It is computed that in England 15,000 persons are annually interred without medical certificates of any sort, while in the North of Scotland this applies to 50 per cent. of the population. No one will demur to the assertion that in

Hosted by Google

most, if not in all, of the European States certification of death is still inadequately provided for, and whilst this is the case many criminal acts will continue to escape detection.

But Dr. JENNINGS'S advocacy is directed against premature burial, and the basis of his contention is the value of the signs of death. Having subjected each to critical examination, he arrives at the conclusion that the only infallible proof is post-mortem decomposition. We do not propose to review in detail all the means, scientific or secular, that have been suggested as proofs of death. Many antiquated popular ideas have long since been rejected as unworthy of serious consideration, but a slight sketch may not be out of place here. The erstwhile common procedure of placing a feather over the nostrils to ascertain if breathing had ceased met with decisive refutation of its value in SHAKESPEARE'S description of the death of King Henry IV. It will be remembered that Prince Henry, who sat and watched his father, exclaimed :—

> "By his gates of breath
> Their lies a downy feather which stirs not;
> Did he suspire, that light and weightless down
> Perforce must move."

But ere the king expired he gathered strength to administer reproof to, and bestow an intensified blessing on, his son. A somewhat similar incident pertinent to the issue of the "breath of life" is to be found in *King Lear*. The aged monarch, bearing the dead body of Cordelia, delivered himself of the imposing words :—

> "I know when one is dead, and when one lives;
> She's dead as earth. Lend me a looking-glass;
> If that her breath will mist or stain the stone,
> Why, then she lives."

These classical presentments are the records of what was then considered as the passage of the Angel of Death. Even yet a procedure to prove the cessation of breathing, and inferentially of life, is sanctioned by some high authorities. Sir HENRY THOMPSON says: "To detect whether a patient is dead or only in a trance, place a shallow vessel brimful of water upon the chest. If there is any life the liquid is bound to be agitated in a greater or lesser degree." We are compelled to subscribe to the reply of Dr. ICARD in his recent work (1897). "The test is untrustworthy, for besides the act of breathing there are other conditions, such as the fermentation of cadaveric fluids and post-mortem diaphragmatic movements, which may cause vibratory movements in the liquid; on the other hand, these movements may be wanting although respiration is going on, by reason of the absolute fixity of the chest wall, the breathing being carried on by the insensible movements of the diaphragm." It may be noted that in the experiment in question it has been recommended to watch the movement of the image of an object mirrored in the water, as well as to observe the vibratory movement of the water itself. The rippling of the surface from actual respiratory movement of the chest would probably be more uniform and rhythmic than if due to an adventitious cause.

The unreliability of the respiratory test led observers to centre their attention on the question of cessation of the heart's beat. Previously to 1846, when BOUCHUT published his researches, made with the aid of the stethoscope, it was difficult, and, indeed, well-nigh impossible, to arrive at a definite conclusion on the matter; and at the present time it is asserted by some that the cardiac pulsation may be so weak as to be unrecognisable by the means at our disposal. BOUCHUT undoubtedly erred in making too short the period of time elapsing after the heart's sounds ceased to be audible which he took as proof of, death. Nevertheless, if an interval of five minutes elapses the presumption of death is great. If no cardiac sounds can be heard after the respiration has apparently ceased for half an hour, it is well-nigh, if not absolutely, certain that life is extinguished.

In discussing the subject under notice it should be borne in mind that after somatic death molecular life, taken in terms of physico-chemical action, continues. Thus the irritability of the muscles is not at once extinguished. The temperature of the body in some cases, and notably where death has supervened upon an acute febrile affection or upon a cerebral lesion, continues to rise after the patient's decease, so too much reliance must not be placed on the body heat taken unconditionally. As regards the rigidity of the body, a careful observer could scarcely be deceived, for in the rigidity of trance the temperature is more or less sustained; moreover, the whole body becomes equally rigid at the same time. If the limbs of a person in cataleptic spasm be flexed the rigidity soon returns, whereas in cadaveric stiffness it re-appears slowly or perhaps not at all. It is impossible to assert that such a ghastly event as burial of the living has never occurred. There are well authenticated cases of bodies having been laid out for interment that yet retained their vitality; still, if the list of alleged burials of the living were subjected to critical examination we opine that it would dwindle to very narrow proportions. We ardently support the reform of death certification. No argument is needed to enforce the desirability—nay, the paramount necessity—of efficient death verification; but we cannot acquiesce in the proposal that no interment should take place prior to the advent of cadaveric decomposition, believing as we do that a conscientious medical observer can verify the decease of a human being before the body is "green in death and festering in a shroud."

Annotations.

"Ne quid nimis."

WORKHOUSE NURSING.

WORKHOUSE nursing seems to have been attracting a considerable amount of public attention lately, and seeing that THE LANCET has played an active part in this arena, we feel it our duty to call the special attention of our readers to this matter. Mr. Ashton, M.P., asked in the House of Commons in May last for a return showing the number of persons occupying the sick wards in workhouses and infirmaries on June 1st, and the number of paid officers, probationers, and pauper helps employed in attending on them. A very large number of figures are given in the return concerning the different workhouses and infirmaries throughout England and Wales. We do not, however, think it worth while to criticise them at any length, because the whole return is the subject of a very serious fallacy. On June 1st the numbers of the inmates of workhouses and infirmaries are at their very lowest, and experienced Poor-law officers generally

Hosted by Google

reckon that there are in the summer very little more than half the number of inmates who are in these institutions during the winter months; and as the paid staff and the number of helpers are not reduced at the slack time of year, the proportion between the patients and the nurses and pauper helpers who attend on them, as represented by this return, is no guide whatever to what really obtains during the rest of the year. If any inferences were to be drawn from these figures as to the adequacy, or rather inadequacy, of the supply of nurses, they would be wholly misleading. "Provided, fifthly, that any pauper of the fourth class whom the master may deem fit to perform any of the duties of a nurse or assistant to the matron may be so employed in the sick wards." The inmates belonging to Class 4 are "women infirm through age or any other cause." These are the words in which the Poor-law Commissioners, by Article 99 of their General Order, dated Dec. 8th, 1847, instructed the masters of workhouses, both London and provincial, in the duties of their office and the classification of paupers. This article was the origin of "pauper nurses," the article which rendered them official; and this, if we mistake not, is the cause of their perpetuation at the present day. The abuses to which it gave rise were the subject of a very exhaustive inquiry initiated by the Founder of THE LANCET many years ago. It is therefore with great regret that we notice that this old and obsolete article is still unrepealed; and it is also with corresponding pleasure that we see that at last the masters of workhouses themselves—namely, those officials with whom these evils are ever present and by whom their rectification should really be initiated—have evinced some interest in the matter. Our contemporary, the *Local Government Chronicle* of April 3rd, contains the report of a meeting of the Workhouse Masters' Association, and prints *in extenso* a paper contributed by Dr. Malden, medical officer to the Tonbridge Union Workhouse. It is too long for us to notice at any great length, but in general terms it has our cordial approval, and we hope that it may be the means of stirring workhouse masters and matrons to a sense of their responsibilities in the way of inducing the guardians to provide adequate nursing for the sick in workhouses. We are amused to notice in the discussion which followed that some of those present seemed to complain that the Workhouse Nursing Infirmary Association was not the right body to carry out this reform. It is true, quite true, that a philanthropic body should not perform the duties of masters of workhouses and guardians of the poor, but if those individuals do not discharge the duties which they owe to the sick poor, surely they cannot complain if other people step in and fill their places. As regards some adverse remarks made against this association—to which, by the way, the speaker owed her training—we have it on the best authority that the association is very careful never to interfere with the internal administration of workhouses so long as a skilled and properly trained nurse is supplied with the means of carrying out her duties thoroughly. The great work which this association has done is pointed out in a later issue of our contemporary, where it is mentioned that during the past eighteen years that body has spent over £3000, collected in voluntary subscriptions, in training and supplying to workhouses and infirmaries nearly 800 nurses.

A CURIOUS VERDICT: A CORONER'S VIEW OF MEDICAL EVIDENCE.

AN unfortunate occurrence happened a few days ago in the Wigan Corporation Baths. A young man, who had gone on the previous evening to have a bath (the ordinary slipper bath), was found by the attendant next morning (when taking a person to have a bath) dead with his head completely under water. An inquest was held in due course, and the jury, without having any medical evidence as to the precise cause of death, found "that death had resulted from failure of the heart's action (syncope) whilst the deceased was having a bath." They further stated that they were hardly satisfied with the evidence given, and as there was a police doctor they would have preferred to have heard some medical evidence in connexion with the case. The coroner asked if they would like the inquest adjourned for medical evidence, but the foreman of the jury thought it hardly necessary. The coroner then said, according to the *Wigan Observer* of the 10th inst., "that where the cause of death was so apparent they considered that it was unnecessary to have medical evidence. In fact, it was like throwing ratepayers' money away, and in that case they considered they were saving it. A medical man would not give evidence as to the cause of death when he was called in after death unless he made a post-mortem examination, which was not only objectionable to the relatives, but rather expensive." In this case, where an unfortunate young man was left in a bath all night, the most searching inquiry should have been held, not only to find out if anyone was to blame for neglect, but to ascertain whether the death was from natural causes or from drowning. Such could not be done without a post-mortem examination; and if the coroner thinks that the sum of one guinea remunerates a medical man for this disagreeable work he is much mistaken. Many medical men would prefer not to make such an examination, but know that it must be done if the true cause of death has to be found. And what is the value of an inquiry like this? If the coroner knew that the man had died from natural causes, why did he summon twelve good men and true away from their businesses? Such an inquiry without a post-mortem examination is useless.

LUNACY IN EGYPT.

DR. JOHN WARNOCK'S annual report on the Cairo Lunatic Asylum for 1896, although only half as long as its predecessor, is, nevertheless, a notable record of continuous progress in the only hospital for the insane which Egypt possesses. Mechanical restraint of every description has at length been completely abolished, and owing to the introduction of pass keys and substantial asylum locks it has been possible to re-arrange the establishment into six sections containing 70 patients each. A new system of drainage has been adopted, so that all foul water now flows out beyond the hospital premises instead of into percolating cess-pits inside the walls. This is, doubtless, advantageous to the institution, but as Cairo is not yet sewered the adjoining ground must necessarily suffer. A great many structural alterations and additions were completed during the year at a cost of £E3573, and equipment valued at £E827 was also added to the existing stock. Many innovations, however, are still required, including a male infirmary, a laundry, additional first- and second-class accommodation, and extension of the section for cases of acute insanity in men. The estimated expense is £E5840, and Dr. Warnock hopes that some at least of the items may be supplied, "notwithstanding the many other claims on the finances of the country." The number of inmates has fallen from 488 to 417. "This is partly due to the cessation of admissions during the cholera outbreak" and partly to the impossibility of properly accommodating more than 420. The "average daily number resident" was 477 (337 males and 140 females). In the course of the year 425 cases were admitted, no fewer than 136 of them being re-admissions, some for the eighth or ninth time; 145 of the new patients bore marks of injury more or less severe, nine among the number having broken ribs. Many of them had "broad scars over vertex, temple, and occiput, due to cauterisation

Hosted by Google

when in their homes," and marks left by ligatures were frequently visible on their wrists and ankles. There is no separate section in the asylum for criminal cases. In addition to ordinary prisoners and persons under police surveillance 23 individuals accused of capital crimes were sent in from the tribunals for observation or treatment. 29 general paralytics were admitted in 1896, against 19 in the previous year, 4 of the number being Greeks. Only one was a fellah; the others were pedlars, servants, artisans, &c. Dr. Warnock thinks it is probable that general paralysis exists in Egypt to a much larger extent than was formerly believed, but does not give the reasons on which this opinion is based. The relation of the affection to syphilis receives support from his observations. "Hasheeshism still remains the most potent cause of insanity in Egypt"; 90 of the admissions were clearly due to abuse of the drug, and there is reason to believe that "the real percentage of male admissions caused by hasheesh is nearer 50." 81 deaths took place during the year, including 23 from tuberculosis and 10 from cholera. The number of foreign lunatics at present in the asylum is 41, chiefly Greeks, Jews, and Syrians. They occupy room which can only be ill spared, but apparently it is impossible to get rid of them. Some of the Syrians are brought to Egypt on purpose to obtain admission, as there is no establishment for the insane in their own country. Dr. Warnock has been informed that some lunatics are kept in Damascus in stone cells, with chains round their necks.

CASTRATION FOR ENLARGED PROSTATE.

THE misery of existence for anyone suffering from enlarged prostate and all the evils which this affection brings in its train have been so universally recognised that it is no wonder that surgeons should have been for some time seeking some method of relief. Prostatectomy is dangerous and oftentimes brings no amelioration of the trouble; therefore, it was proposed by Professor White of Philadelphia to cause shrinking of the prostate by removal of the testicles, a result which undoubtedly sometimes does follow. The operation, however, is liable to be followed by various unpleasant symptoms and in some cases by death. Mr. F. E. Fremantle, of Guy's Hospital, recently read a paper before the Physical Society of that hospital, wherein he has carefully collated all the published literature on the subject so far as he could, and has compared the relative advantages of bi-lateral castration, uni-lateral castration, and excision of the vas deferens. Shortly, his conclusions are as follows:—1. Removal of the testes in cases of hypertrophied prostate causes a relief of symptoms, and usually a reduction of the hypertrophy analogous to the effect of oöphorectomy on uterine fibro-myomata. 2. Shrinking of the prostate is probably due to the removal of some sub-conscious reflex stimulus, normally conveyed to it from the testes by way of a lumbar spinal centre. 3. This is more especially suggested by the fact that removal of one testis will sometimes cause a corresponding one-sided shrinking of the prostate. 4. The immediate or rapid relief of symptoms in these cases is almost entirely due to relief of congestion and œdema in the lymph-spaces and venous plexuses of the urethra and prostate. 5. Double castration is less dangerous than prostatectomy, and will cause an amelioration of the chief symptoms in about 80 per cent. of the cases. 6. The mortality is greatly increased by operating on patients with advanced kidney disease, and operation in early stages will be performed with a better chance of complete cure and almost without risk to life. 7. If castration be refused, after a firm and honest statement of the dangers of refusal, excision and torsion of the vasa deferentia, although of less certain efficacy and of doubtful moral expediency, may with regret be recommended. Mr. Fremantle's paper, which was published in the *Guy's Hospital Gazette*, is a carefully compiled summary of present opinion upon the subject, and although, as the writer himself says, it does not pretend to any originality, it will be found useful for reference.

KING'S COLLEGE SCHOOL.

THE Council of King's College, London, has sanctioned a reduction of 20 per cent. in the fees of all boys who pass after not less than five terms of study from King's College School into the medical school. King's College School has recently been removed from the Strand to Wimbledon Common, where a large mansion has been purchased standing in what we are informed is an unimpeachable site. Certainly Wimbledon is a thoroughly pleasant and healthy suburb, in every way suitable for school premises, and we may anticipate for the school in its new quarters a maintenance of its good moral tone and high level of scholarship.

DRINKING A QUART OF WHISKY.

THE folly, in a young man aged twenty years, of drinking a quart of whisky for the wager of £1 would seem incredible were it not that the literature of medical jurisprudence supplies us with several similar instances. One is recorded by Professor Christison in his book on Poisons—that of a London cabman who, for a bribe of 5*s*., drank at a draught a whole bottle of gin. In a few minutes he dropped down dead. The same high authority says that such accidents are not infrequent in Scotland. He gives one instance of death in four hours. The victim was a man who had stolen a bottle of whisky, and as the surest way which occurred to him of escaping detection drank it all. In the case recently reported death seemed to occur in about eight hours. There was a difference of opinion at the inquest as to the complicity of others. It was not proved that the publican was aware of the use to be made of the drink which he supplied. It would seem to be but right that the other party to such an experiment should be held responsible for the consequences.

EPIDEMIC SMALL-POX IN NEW ORLEANS.

AN interesting statement, illustrative of the malignancy of small-pox, is contained in the Report of the British Consulate on the Trade of New Orleans for 1896. The statement consists of an extract from the record of the small-pox outbreak in New Orleans in 1895-96, and is from the pen of Dr. Woods, the chief sanitary inspector of the city. The extract is so pithy and significant that we have no hesitation in reproducing it as given in the Consular Report: "In February, 1895, a man came here from Arkansas, and afterwards developed a well-marked case of variola. At that time the disease existed all over the Eastern Arkansas and Western Tennessee counties. Otherwise than in a very general manner we could not further or more definitely trace the origin of the disease. From this case others in due season developed. In February, 1; in March, 4; in April, 3; and in May it reached the alarming proportion of 58 cases; in June there were 36 cases. After the first case in February the authorities vaccinated all parties living in the infected localities—that is, all who would accept vaccination. The clothing, bedding, and wearing apparel, except those worn by the patient when sick, and the bed upon which he slept, were subjected to boiling water for thirty minutes, and afterwards left over night in a bichloride solution of 1 in 1000. Those articles and fabric coming in direct contact with the patient were destroyed by fire. All carpets and matting in the patient's room were also destroyed by burning. The walls, floors, all furniture and fixtures, the galleries, and even walks, yards, and outhouses, were sprayed or otherwise washed down with a bichloride solution of 1 in 1000. The interior of the house, after thoroughly closing the openings and chinking all cracks, was subjected to sulphur fumes for nine hours, with from 5 to

Hosted by Google

7 lb. of sulphur candles to 1000 cubic feet of air space. With these rigid measures observed in every instance of the disease the outbreak was in a manner controlled during the summer months of 1895, but with the advent of winter the disease seemed to take a fresh start, having been re-introduced from time to time from the country parishes where it existed to quite an extent. In the fall of 1895 a very rigid vaccination campaign was inaugurated by the Board of Health, and the work was not stopped until the entire city had been canvassed by a large and efficient corps of physicians, who systematically, by districts, went from house to house offering and urging free vaccination. During this campaign 53,437 people were vaccinated and re-vaccinated. After this systematic vaccination campaign was over, and the influx of darkies from the country parishes had ceased, the disease steadily decreased. In March, 1896, we had the greatest number of cases of any month during its prevalence, reaching a total of 334 cases. Since the introduction of the disease in February, 1895, we have had 1126 cases with 291 deaths, making a death-rate of 25·84 per cent."

ICHTHYOL IRRIGATION OF THE URETHRA FOR GONORRHŒA.

WE publish in another column an interesting account of eighty-two cases treated in this way which have been recorded by Dr. Werner. Gonorrhœa so often proves intractable and the complications and sequelæ connected with it are so numerous and severe that every new method employed in its treatment is worthy of careful attention. The intractability of the disease is really due to the difficulty which exists in bringing an efficient antiseptic in contact with the gonococcus without injuring the mucous membrane. Janet's method of irrigation is especially useful in that the fluid pressure distends the urethra, and so obliterates the folds of the mucous membrane which shelter the organism from ordinary injections; but the method is by no means free from risk, for the inflow of the solution used may carry gonococci with it, and so cause not only an extension backwards of the urethritis, but also cystitis and epididymitis. Ichthyol is a fairly good antiseptic, and as the cases quoted show, can give much better results than the permanganate of potassium originally used by Janet.

SWINE FEVER.

THE Departmental Committee of the Board of Agriculture appointed to inquire into the etiology of swine fever have issued their second Report, containing experimental and other evidence of great interest. The committee refer to pneumonia of the pig and to swine erysipelas, two diseases distinct from swine fever, and incidentally referred to in the first Report. Pneumonia of the pig is recognised by American veterinary surgeons as a disease distinct from swine fever and is regarded as identical with the disease known in Germany as *schweinseuche*. The same bacterium has been found in both countries in association with this disease. The committee obtained cultures from Dr. Salmon of America and from Professor Schütz of Germany, but they found that the cultures had only a feeble effect on pigs, though highly virulent to rabbits and pigeons. The committee isolated a bacillus, indistinguishable from the *schweinseuche* bacillus, from the lungs of English pigs affected with pneumonia complicating swine fever, and they conclude therefore that the pneumonia of the pig, which is occasionally encountered as an independent disease and sometimes in association with swine fever, is to be ascribed to organisms which are "generally saprophytic and only in particular circumstances able to multiply in the air passages, and thus induce pneumonia.' With regard to swine erysipelas the committee have not been able to find any outbreak of the disease in an acute or epizootic form in the United Kingdom, but they made the interesting discovery that the bacillus of swine erysipelas was present in twenty-eight out of thirty-eight cases of verrucous endocarditis. Further inquiry did not lead the committee to conclude that the frequently encountered cases with chronic heart disease represented pigs that had survived an acute attack during an outbreak of the disease; and attempts to infect healthy pigs by feeding them with blood or cardiac vegetations containing the bacilli, or with artificial cultures, gave in every case negative results, though the bacilli were virulent to mice and pigeons.

THE HERMITE PROCESS AT BOMBAY.

THE Hermite process, which consists of the use of electrolysed sea-water for the deodorising and sterilising of sewage, and which was reported upon by THE LANCET Special Analytical Sanitary Commission on the Hermite Process of Sewage Treatment by Electricity,[1] has already been tried in Worthing, Netley Hospital, Havre, and elsewhere, and is now about to be adopted at Bombay. The plant has been erected at Carnac Bridge and an agent has arrived to superintend the experiment. The Hermite system is, we should imagine, specially adapted to a city like Bombay, where the sewers are defective and the sewage can be run into the sea.

THE SURREY COUNTY HOSPITAL AND HOME VISITS.

THERE has lately been much discussion in Guildford as to the visiting by members of the Surrey County Hospital staff of sick persons, patients of the hospital, at their own homes. A scheme has been considered by which the hospital authorities are to work with the townsmen who are promoting the Jubilee commemorations, and the townsmen offer £50 annually to the hospital if 200 tickets for home visits are supplied and an out-patient letter given with each. The chief opposer of the scheme argued that it would fall through by the introduction of out-patient tickets, that £50 for 200 tickets was a most inadequate sum, that the country subscribers would say that the town of Guildford obtained too much advantage, that it was the duty of the committee to oppose a scheme which would tend to pauperise a portion of Guildford, and that the home visits were likely to introduce infection into the hospital. The hospital committee are greatly in favour of the scheme being adopted. With regard to the objections given above we agree with them all except the last. Unless the staff of the hospital are to be debarred from all private practice, we do not see why the visiting of a poor patient should be more likely to introduce infection than a visit to a patient who is better off. Disease is no respecter of persons, station, or wealth, and a medical man is as little likely to carry infection from a hovel as from a palace. As to the practice of hospital staffs visiting hospital patients at their own homes, it is one of which we do not approve; hospital patients when they are discharged from the wards should cease to be hospital patients other than as out-patients.

THE ELECTRO-CAUTERY AS A HÆMOSTATIC.

A HÆMOSTATIC application of the electro-cautery is reported by Dr. Alexander J. C. Skene in the *New York Medical Journal* of March 27th. This consists in its employment instead of the ordinary torsion artery forceps and the compression forceps. In the case of the artery forceps a thin platinum plate is attached to the distal extremity of either blade, but isolated from it by a sheet of mica. The proximal ends of the plates are attached to copper wires, also isolated, which pass along the proximal end of the forceps

[1] THE LANCET, May 26th, 1894.

Hosted by Google

through a vulcanite case and communicate with a battery. It is sufficient, says Dr. Skene, that one blade only be thus electrically fortified. In the case of the compression instrument a modification of the original plan is introduced, a platinum wire passing inside a flat watertight metal chamber applied along the inner side of one blade to the distal end of the instrument, where it is attached to a platinum plate. It is, of course, isolated. At its proximal end it is connected with a copper wire which traverses a vulcanite case and passes, together with a wire attached to the handle of the forceps, to the battery, as in the artery forceps. In order to develop sufficient electrical resistance the platinum wire in the metal chamber is made to take a zigzag course. Dr. Skene has also devised a clamp with the electrical modification. He states that by this means the required degree of heat—170° to 190° F.—can be attained very quickly, and that the apparatus can be easily adapted either to a suitable battery or to the current from the electric light mains. He has made use of his invention in treating the pedicle in ovariotomy, in operations on the broad ligament of the uterus, and in vaginal hysterectomy. As yet he has not employed it in abdominal hysterectomy, but he is confident that it is suitable for this operation also.

THE SUPPLY OF STIMULANTS AT THE GAOL HOSPITALS IN NEW SOUTH WALES.

EARLY in 1895 the Comptroller-General of Prisons brought under notice the extravagant use of stimulants in the hospital of one of the large gaols, and a report was obtained from the then Government medical officer on the subject. It was recommended that white spirit, diluted to 40°, should alone be furnished in response to requisitions for alcohol. This recommendation was approved. Two visiting surgeons to gaols—Mr. Carruthers and Mr. O'Connor—have recently objected to using this white spirit, and wish to be allowed to use their discretion as to what form of stimulants should be ordered, and Dr. Ashburton Thompson, the Government medical officer, has sent in a further report on the subject. He had the brandy previously supplied under contract to the gaols analysed, and found that it was composed almost entirely of the "white spirit" to which objection was taken, coloured and flavoured. It was not brandy from the grape, but a spirit of less certain wholesomeness than that to which Mr. Carruthers and Mr. O'Connor objected. He adds that everyone interested in the matter knows that the spirits of commerce very seldom have the origin their names specify, and the compound in question is everywhere accepted in the course of ordinary business as "brandy." As the complaint was that the medical officers were compelled to give up the contract article, now shown to be a more or less impure "white spirit," Dr. Thompson says, "nothing remains to be considered." Whether everyone will agree with him in this opinion is another matter.

POISONOUS ICE CREAMS.

EVIDENCE comes almost day by day, at any rate in the summer season, of the desirability of placing the manufacture of ice creams under definite control. There is no reason why an inspector should not be appointed to seize any materials intended for the preparation of ice cream that prove to be unfit for food, just in the same way as meat or any other article which is in an unwholesome state may be seized. As was shown in the report of THE LANCET Commission on the Sanitary Condition of the Italian Quarter as far back as Oct. 18th, 1879, the surroundings under which cheap ice creams are very commonly made are often loathsome in the extreme, and it is not surprising that recent bacteriological inquiry has demonstrated the presence in them of the organism that is a normal inhabitant of the human bowel, and it is well to bear in mind that any objectionable taste that the ingredients may have is not noticeable owing to the numbing effect of cold upon the tongue. Only this week an inquiry was held touching the death of a child, aged fourteen years, who, four days after partaking of some ice cream obtained from a barrow in the street, died from ptomaine poisoning. The post-mortem examination showed that all the organs were healthy except the stomach, which was greatly congested, evidently by the action of an irritant poison. A verdict of accidental death was returned. There is little doubt that the ptomaines were derived from bad eggs or perhaps highly decomposed milk. Seeing the great number of innocent juvenile partakers who are to be found round the barrows almost every day, it is high time that ice creams and the ingredients employed in their manufacture should be subjected to the same control as are unsound meat, fruit, and tinned and other articles of food.

THE LATE MR. JAMES BLAKE BAILEY.

IT is with great regret that we announce the death of Mr. J. B. Bailey, the Librarian of the Royal College of Surgeons of England. Mr. Bailey, who was in his forty-ninth year, had for some time been suffering from symptoms of malignant disease of the liver, and no hope of his recovery had been entertained for the past few weeks. He had held the post of Librarian to the College for the period of ten years, and previously to accepting that appointment had been the Librarian to the Royal Medical and Chirurgical Society since 1884. Before this date he had held the office of Librarian of the Radcliffe Library at Oxford under Sir Henry Acland. Mr. Bailey's loss will be very much felt by all who have ever come into contact with him. He was an admirable man for his post, always able and willing to give information, and devoting his whole time to his books. He was never tired of hunting among the archives of the College, and brought to light many a forgotten pamphlet or book of interest, which he sometimes republished and illustrated with notes that showed a keen critical and literary insight. His latest publication was the interesting little book, "The Diary of a Resurrectionist."

THE MICROBE OF CHICKEN CHOLERA.

THE invasion of the various colonies of Australia by rabbits is one of the most serious difficulties with which agriculturists have to contend, and numerous attempts have been made to get rid of these animals by trapping, by a "poll-tax," by phosphorus poisoning and in various other ways. Some time ago it was suggested that Pasteur's fowl cholera organism or Koch's rabbit septicæmia organism should be introduced into the colonies with the object of killing off the rabbits by a kind of artificial epidemic. It was objected, however, that the introduction of this organism might do more harm than good by killing all the poultry and perhaps not getting rid of the rabbits. Mr. C. J. Pound, Government Bacteriologist to the Colony of Queensland, now states in a report presented to the Houses of Parliament of the colony that fowl cholera is already present in the colony. This being the case he has taken the opportunity of carrying on a series of experiments with the fowl cholera organism, as a result of which he is convinced that by the judicious use of food mixed with this organism in dry weather he will be able to set up an epidemic amongst rabbits, even those in a wild state, which would in time mitigate to a very marked degree this rabbit plague, and he recommends his Government to give permission to agriculturists to use this organism as a rabbit poison. Whether this can be carried out on a large scale, and whether it would be successful if carried out, still remains to be proved; but from all accounts the

Hosted by Google

rabbit nuisance has reached such proportions that any method of keeping down these "vermin" will probably be tried in Queensland; whilst, should it prove successful, it will be hailed with almost as much delight as that with which Koch's method for treating rinderpest has been received by the South Africans.

LONDON POST-GRADUATE COURSE.

ON Monday, May 3rd, the summer term will commence, and will include courses at Blackfriars (Skin), King's College (Bacteriology), London Throat Hospital, Parkes Museum, Institute of Preventive Medicine (Urine Testing), and Cleveland-street Infirmary (General Medicine and Surgery). All information will be afforded and fees received by Dr. Fletcher Little, secretary, 32, Harley-street, London, W.

THE ROYAL COMMISSION ON TUBERCULOSIS.

WE understand that the Royal Commission on Tuberculosis has been much impressed with the general concurrence amongst the witnesses who have been heard as to the necessity of establishing public abattoirs wherever this is possible, both in the interest of the public health and to protect graziers and butchers against the present want of uniformity in the seizure of carcasses on account of tuberculosis. Several members of the Royal Commission have, therefore, commenced a tour of inspection of foreign cities to study this question and to learn generally what action is taken abroad both as to tuberculous carcasses and tuberculous milch cows. The first cities to be visited are Brussels, Cologne, Berlin, and Leipzig. Other visits will probably follow later.

THE MUZZLING ORDER.

AN impassioned correspondence has been going on in the daily press about the recent muzzling order and the Board of Agriculture has been assailed with a virulence which certainly seems excessive when we remember what slight cause it has given for such abuse. On one point we can agree with the objectors to the order, and that is we consider that the muzzling order ought to have been made universal throughout the kingdom, and that on the expiration of the appointed period a strict system of identification of dogs and their owners should be inaugurated by means of registration and the wearing of a marked collar by the dog. But in most ways many dog-owners seem to have completely lost their heads and to have imported political bias into the question, which is quite beside the mark. Anyone who is so foolish as to say that a Government or a candidate will lose his vote on account of this order is quite unfit to exercise the franchise at all. If these silly persons had ever seen a case of hydrophobia they would think no means too stringent to stamp out such a fearful disease, although we quite agree that the present methods of procedure are inadequate.

MORTALITY STATISTICS AMONG FOREIGNERS IN SHANGHAI.

THE annual report of Dr. J. Taylor Grant, municipal surgeon and medical officer of health, shows that during the year 1896 there were 141 deaths of foreigners registered in Shanghai, including 4 adults whose bodies were brought to Shanghai for burial and 2 stillborn infants. Taking the whole foreign population, resident and non-resident, including the French Concession and the foreign shipping, this gives an annual death-rate of 22 per 1000, as compared with 23·5 in the previous two years and 18·4 in 1893. Of these deaths, 19 were due to small-pox, 14 to tuberculosis, 12 to drowning, 10 to cholera, 10 to enteric fever, 1 to cholera morbus, and 2 to opium poisoning. As far as can be gathered from the native returns, only 18 deaths of natives were due to cholera during the past year, as compared with 928 in 1895. Among the natives 316 deaths are certified as due to small-pox. In the native hospitals vaccination is performed regularly twice a week by the native practitioners, whose returns show that the natives in and around Shanghai appreciate it more each year, and that 7160 vaccinations were performed in the city alone during 1896. Preparations were made against a threatened invasion of plague, but the disease did not spread to Shanghai. During September and October dengue prevailed extensively throughout the Settlement. This specific eruptive disease attacked alike foreigners and natives, adults and children, but in no case among foreigners was there a fatal termination.

OYSTERS AND DISEASE.

AT their meeting on Thursday, April 15th, the Brighton Corporation drafted the petition which they intend to send to the Local Government Board asking for a Bill to control the dissemination of oysters and other shell-fish proved to be contaminated by sewage. The support of other municipalities is to be sought in the matter. Speaking first of the "increasing bulk of evidence" that enteric fever is communicated from this source, the memorial goes on to say that certain of the memorialists have had within their districts cases traced to this cause. The report of Dr. Bulstrode, it is claimed, proves the danger and the need of remedial measures. It is suggested that these latter should include the giving of powers to local authorities similar to those of Section 4 of the Infectious Diseases Prevention Act, 1890, in the case of milk—i.e., to prohibit the supply within their district of any shell-fish from any water proved to the local authority to be contaminated by sewage, the consumption of such shell-fish being proved to be, or being likely to be, dangerous. An appeal to the Local Government Board from the local authority is suggested. Further, they ask that power to totally close oyster-beds or ponds on the representation of the local authority shall be vested in the Local Government Board.

THE Order of the Double Dragon has been conferred by the Emperor of China on four of the surgeons who took part in Red Cross hospital work during the Chino-Japanese war. The names of the recipients of the honour are—Thomas Brander, M.B., C.M. Edin., Dugald Christie, L.R.C.S., L.R.C.P. Edin., Charles De B. Daly, M.B., M.Ch. Dub., and D. C. Gray, M.B., C.M. Glasg.

THE East London Hospital for Children, Shadwell, has now been recognised by the Conjoint Board for England as a place of instruction for students, at which six months of their fifth year under the new regulations may be spent in clinical work. Full information on all points may be obtained from the secretary at the hospital.

THE annual dinner of the Army Medical Staff will be held this year in the Whitehall Rooms, Hôtel Métropole, at 7.45 P.M., on Monday, June 14th, the Director-General in the chair, and it is hoped that the Army Medical Staff band from Aldershot will play during dinner.

WE understand that Mr. Bennett May, Professor of Surgery in Mason College, Birmingham, is an intending candidate for the vacancy on the Council of the Roya College of Surgeons of England caused by the death of Mr. Oliver Pemberton.

THE Prince of Wales will open the new buildings of the Sarah Acland Home for Nurses at Oxford on May 12th.

The Lancet Special Commission
ON THE
METROPOLITAN WATER-SUPPLY.

IX.[1]

Historical.

BEFORE describing the three companies which still remain to be reported upon it will be convenient to give a few more details of the past history of the water-supply of London, a partial *résumé* of which has already been given.[2]

In the early period of its history London, as we have seen, was supplied by water from the River Thames, from streams which ran through the city and from a number of wells. The accompanying map is reproduced from one in the Grace collection now in the Print Room at the British Museum. It shows the probable position of the wells and streams in and near the City of London in the year 1000. Stow says that at one time Walbrook was "a fair brook of sweet water, which came from out the north fields through the wall and midst of the city into the River of Thames, and which division is till this day constantly and without change maintained."

There was, says Stow, "a long bourne of sweet water, which of old time, breaking out into Fenchurch-street, ran down the same street and Lombard-street to the west end of St. Mary Woolnoth's Church." This was the Langbourn, and there is no doubt as to the course of this stream, which is correctly given in the map. As to the Shareborne, it seems by no means certain that the map is correct. Stow says that from the west end of St. Mary's Church the Langbourne, "turning south and breaking into small *shares*, rills, or streams," gave the name to Shareborne-lane. The site of Crowder's Well is now Well-street, Jewin-street. At the early part of the eighteenth century the water of this well was, according to Strype, "esteemed very good for sore eyes to wash them with. ..... And some say it is very good for men in drink to take of this water, for it will allay the fumes and bring them to be sober."

River pollution.—The pollution to which the streams were subject gave rise at quite an early period to complaints, and river pollution was an object of legislation in the Parliament which met at Carlisle in the twenty-fifth year of the reign of Edward I. The Earl of Lincoln complained that the pollution of the Old Bourne had become unendurable in consequence of the filth from the tanneries situated on the banks of the stream. The citizens were ordered to cleanse the river. The people who in early times made a trade of getting water from the river had not always a very easy task in consequence of the condition of the banks. There is a case recorded in which one of these people was drowned in trying to land. The report of the inquest is in the City archives.

Supply to the religious houses.—Before leaving the early history of the London water-supply it may be worth while to mention that the religious houses had, in most cases at any rate, an independent and good water-supply. St. Peter's Abbey at Westminster was supplied by water from Hyde Park and the Charterhouse by water derived from Islington. The Priory of St. Bartholomew's had also a good water-supply. The destruction which occurred at the Reformation and the breaking up of the religious houses interfered for a time with some of the purest sources of supply.

The earliest water businesses.—The first time in the history of London in which the supply of water became a considerable business was undertaken by Moris, and to this reference has already been made.[3] The other early water businesses which were started for the supply of places north of the Thames were the New River, the York Stairs, and two smaller ones in the East-end. Of these the New River Company is the only one which still exists in recognisable form, and we propose going into its history later. The East-end businesses are now represented by the East London Waterworks, in connexion with which their story will be told, and we need here only say a few words as to the London Bridge and the York Buildings Waterworks.

The London Bridge Waterworks.—Little need be added to the history already given of the early career of the London Bridge Works. Every drawing of Old London Bridge shows the water-wheels, and the *Philosophical Magazine* gives an

[1] Nos. I., II., III., IV., V., VI., VII., and VIII. were published in THE LANCET of Feb 20th and 27th, March 6th, 13th, 20th, and 27th, April 3rd and 17th, 1897, respectively.

[2] THE LANCET, Feb. 20th, 1897.

[3] THE LANCET, Feb. 20th, 1897, p. 541.

Hosted by Google

account of the pumps. We cannot do more here than give dates at which the arches of the bridge were given up to the business[4] and pass on to describe the state of the undertaking at the early part of the present century. The quantity of water supplied by the London Bridge Company in 1810 was estimated at something between 3,000,000 and 4,000 000 gallons daily, and the water-wheels worked about twenty hours each day. When the tide was very low less water was raised by the wheels and the quantity was made up by working a steam engine. The superintendent of the Company gave a somewhat depressing account of the business in the year 1821. They had at that time a very "strong enemy" against them, which had taken away many of their customers. "They were in a state of pauperism and much to be pitied." The strong enemy was the New River Company, which had the power of raising water higher than the London Bridge Company could possibly do. The new fashion of building high houses was disastrous to the Company, because cisterns and water-closets were placed at an unreasonable distance above the ground in the new buildings. The pipes used by the Company were made of wood, and they had not enough money to replace them by iron ones. They were unable to supply water at a higher level than the second storey of a house. The superintendent of the Company would not admit that the water supplied was of a bad quality, and he said that in many instances distillers took it in preference to any other, but he admitted he never thought of drinking it. The ebb tides brought down a considerable quantity of soil from the rivers which ran into the Thames and the water was frequently foul, but after it had stood in a cistern for twenty-four hours it became "finer than any other water that could be produced." For his own supply the superintendent had two large cisterns, and by drawing out the water alternately every other day he had "as clear water as could be imagined." The rates charged for supplying the tenants of the London Bridge Waterworks varied according to the amount supplied, from a minimum of less than £1 to a maximum of over £20 per annum. The total number of customers was a little over 10,000, and sixty-eight public buildings were supplied. The method of arranging as to the price charged to customers was that the surveyor first examined the premises closely and reported to the superintendent what he thought the consumption was likely to be and the size of the service pipe. A price was then fixed, and if in the course of time it was found that the consumption was more or less than had been estimated, an abatement or increase in the sum charged was made, according to the circumstances of the case. Brewers, stable-keepers, and some other tradesmen were subject to an extra charge. The amount of water considered necessary for a daily supply to a house was one butt, and any quantity above that was considered an "extra service."

With regard to the ultimate failure of the London Bridge Waterworks it may be said to have been chiefly due to the fact that the New River Company were able to supply water at a higher pressure. which enabled them to force it to the upper storeys of the London houses. The London Bridge Waterworks were destroyed on the demolition of Old London Bridge.

The York Buildings Waterworks.—In the reign of Charles II. a patent was granted to allow waterworks to be made to supply the West-end of London with water from the Thames. The undertaking was called the "York Waterworks," and the premises used occupied part of the site of old York House. The original works were destroyed by fire in the year 1690. In 1691 an Act of Parliament was obtained by which the proprietors of the York Waterworks were incorporated under the style and title of the "Governor and Company of Undertakers for raising the Thames water in York Buildings." In the early part of the eighteenth century the company did not confine the business to water; they speculated largely in land. A number of forfeited estates which had belonged to Scottish Jacobites were bought up at a cheap rate, with the immediate result that there was an enormous increase in the market value of the shares (£10 shares became worth £305) The works were situated at the bottom of Villiers-street, under which the chief reservoir extended. Water was supplied to Piccadilly, Whitehall, and Covent-garden, and the intervening streets. The number of tenants supplied by the York Buildings Company was just over 2000 in 1804; in 1814 it was 2740, and in 1818 2636. It was perhaps rather unfortunate for this Company that there was a fire in the district supplied by them at a time when they were unable to supply water because their own boiler had burst. The fire proved fatal to two or three people, and the fact that there was no water-supply to quench it appears to have made the Company somewhat unpopular. The Company was finally ruined by the competition of the newer companies. Some of the tenants went to the New River Company, some to Chelsea, and some were supplied by the Grand Junction Company. The York Buildings Company ceased to exist in 1818. They leased their pipes to the New River Company and sold their business for a fixed annual consideration. Before that time the Company had been losing money in accordance with the prophecy of a financial poet:—

> "You that are blest with wealth by your Creator,
> And want to drown your money in Thames Water,
> Buy but York Buildings, and the cistern there
> Will sink more pence than any fool can spare."

[4] The lease of the first arch of London Bridge was granted by the Lord Mayor and Commonalty in the year 1581 for a period of 500 years. In 1583 the second arch was granted for a period of 500 years from that date, and a lease of the fourth arch was given in 1701 for a period of 381 years. In 1761 the third arch from the north was granted for a period of 321 years; and, finally, in 1767, the fifth arch from the north end and the second arch from the south end were let on lease to the company for 315 years. The arch on the south side of the bridge was used for putting up a pump for the supply of Southwark.

ANNUAL REPORT OF THE SANITARY COMMISSIONER OF THE GOVERNMENT OF INDIA FOR 1895.

[FIRST NOTICE.]

THESE reports always afford much excellent reading in the way of information derived from various sources—Continental and British—bearing upon the etiology and pathology of disease, in addition to furnishing a public health record of the military and native populations of India. It is to be regretted that their publication has to be delayed until the facts which they chronicle are no longer fresh, but have been supplanted by other and more recent occurrences. It cannot, we presume, be otherwise in regard to official documents, the value of which mainly consists in their accuracy, and which are based upon information and tables derived from various centres. India has, as we know, been passing through a most serious ordeal of late; plague, pestilence, and famine have altogether absorbed public attention and for a while obliterated other and lesser evils from consideration. But there is a great deal of very interesting material in these annual records. The report for 1895 is less voluminous than its predecessors. Acting in accordance with the instructions and suggestions of the Army Sanitary Commission the tables appear in a new and simpler form; they have been reduced exactly by one half, and yet, owing to a process of re-casting and re-arrangement, nothing of importance has, we are told, been omitted; on the contrary, a considerable amount of fresh information has been furnished.

The changes introduced in this respect are numerous and in our opinion an improvement. Among them we may mention that information regarding the distribution of some entozoa is given for the first time, a column has been added to Table XIV. (an important table) showing the number of men added to each regiment by arrivals in India during the year. This is of importance, because, though a regiment may have been a certain number of years in India or at any particular station, yet the actual men in the regiment do not remain the same. A new feature also is the inclusion in one of the tables dealing with European troops of the constantly sick from each disease.

The health of the European army in India, so far as the admission and death-rates are concerned, was better in 1895 than in the preceding year. The chief causes of admission were venereal disease and ague; the former caused 36 per cent. and the latter 23 per cent. of the total sickness. The chief causes of mortality were enteric fever (which caused 44 per cent. of the total deaths), hepatic abscess, and dysentery. Contrasting the past and present mortality of European soldiers in India, reference is made to a statement that the ratio for the period from 1800 to 1830 was 84·60 per 1000; from 1830 to 1856, 56·70; from

Hosted by Google

1869 to 1878, 19·30; from 1879 to 1888, 16·02; and the ratio for the period from 1889 to 1894 was 15·91 per 1000 These figures serve to show very satisfactorily the progressive decrease which has been taking place in the mortality of the European army serving in India. The subject is pursued somewhat further and somewhat more in detail in the Sanitary Commissioner's report in connexion with the mortality from certain diseases for India as a whole from 1870 to 1895 and for the Bengal Presidency from 1858 to 1894, the last year in which this Presidency existed as a separate command. Some of the facts and statistical data are interesting. The earliest year for which statistics are available for India as a whole is 1870. In that year the short service system was inaugurated in England and is presumed to have begun to affect India seriously from 1877. There are no records of enteric fever in the Sanitary Commissioner's office before 1870, although it appears from 1861 onwards in the Army medical blue books. There can be no doubt, however, about the previous existence of the disease in India, but it was returned under the head of other fevers. The increase of enteric fever and venereal disease in India is largely associated with the short service system. Those of our readers who are interested in the subject of the past and present history of disease in India must refer to the tables in the report for themselves; we may content ourselves with merely recapitulating some of the points and quoting the following remarks:—

"The increase in ague may be due to exposure on active service and to the addition to the empire of large malarious regions on the north-western and eastern frontiers. The increase in mortality from respiratory diseases is partly certainly due to the epidemic of influenza, which has not left the country since it first appeared in 1890. The decrease in cholera, scurvy, and some other diseases may be put down to improved hygiene. The decrease in remittent and simple continued fever is probably mostly due to change in diagnosis and transfer to the head of enteric fever. Hepatitis was shown by Dr. Bryden to be a disease of degeneration, a disease of the old soldier. Its diminution appears, therefore, to be a good result of the short service system."

Passing over the subjects of influenza, cholera, small-pox, and the various forms of malarial and the simpler kinds of heat fever among the British troops for 1895 we come to that scourge of the young soldier and officer serving in India—enteric fever. The remarks on this subject, the references to its literature, and the results of bacteriological researches in the report under review are very full and worth reading. We are told that "increased experience has not, on the whole, made the bacteriological investigation of diseases easier. The progress of knowledge has revealed how little is known, the characters of many bacteria do not appear so sharply defined as at first, and identification has become a complicated and laborious process." There is no need to discuss the relation of the prevalence of this disease to the susceptibility of the material supplied to India under the short service system, because that is a matter which has already been threshed out, and occupies an accepted and stereotyped position in official reports from India. It does not, after all, carry us very far. What we want to know is something more precise about its assigned cause, how to detect the typhoid fever bacillus, its life-history, the channels by which it effects its entrance into the body, and the way to prevent it doing so. If we may judge from statistical data and making every allowance for differences attributable to an improved diagnosis we are, notwithstanding all our efforts, still far from having attained success in devising practical measures for preventing or limiting its spread. There are too many subjects in the Sanitary Commissioner's report to be dealt with, even cursorily, in the limits of a single notice, and we must therefore defer our remaining remarks.

NEW SANITARY BY-LAWS FOR LONDON.

UNDER date Dec. 15th, 1896, the London County Council, under the Metropolis Management Act, 1855, are proposing to issue some new sanitary by-laws. In a laudable endeavour to add, if possible, to the utility of what promises to be a very valuable addition to the cause of sanitation in the metropolitan area, Dr. James Edmunds, medical officer of health for the Vestry of St. James, Westminster, and Mr. Henry Monson, the vestry surveyor, have issued a report to their vestry, which was approved and adopted on Feb. 26th, 1897, and printed. Their example might well, and doubtless has been, followed by other vestry officers, as criticisms from such sources, whether accepted or not, cannot but be of value to those who have the responsibility of framing such by-laws and who have the welfare of the public at heart.

The following is a brief outline of the intended by-laws, with the aforesaid criticisms in a condensed form, together with a few of our own comments upon each. The agreement between the mode of procedure advocated by THE LANCET Special Commission on the Relative Efficiency and Cost of Plumbers' Work[1] and the proposed new by-laws is very noticeable.

SUMMARY OF PROPOSED BY-LAWS.

By-law 1 deals with the trapping of subsoil drains ultimately communicating with a sewer, and proposes to ventilate their disconnecting traps only.

By-law 2, paragraph 1, treats of the disconnexion over gulleys of all rain-water pipes; and paragraph 2 directs that these rain-water pipes are to be exclusively used for the passage of rain-water.

By-law 3, paragraph 1, regulates the nature and construction of all soil drains communicating with a sewer; paragraph 2 relates to their thickness and weight in relation to their diameter; paragraph 3 determines the size of and the manner of laying them, the jointing, &c., also as to testing with water; paragraph 4 declares that no drain shall pass under any building unless any other mode of construction is impracticable; paragraph 5 prescribes for the laying of any drain which shall pass under a building, the same to be laid in a direct line and embedded in and covered with concrete; paragraph 6 defines the composition of the concrete to be used; paragraph 7 provides as to the treatment of iron drains fixed above the surface of the ground; paragraph 8 refers to access to drains passing under a building; paragraph 9 decides as to the trapping of all inlets to a drain other than ventilating pipes, and prohibits the use of bell-traps, dip-traps, and D-traps; and paragraph 10 indicates how drains passing under any wall are to be protected.

By-law 4 insists upon the provision of and fixes the position for, and also the means of access to, the disconnecting traps in main drains.

By-law 5 disallows the use of any right-angled junctions in any drain.

By-law 6 assigns the means to be used for the efficient ventilation of the drains communicating with a sewer. Paragraph 1 ordains that two untrapped openings be provided in one or other alternative ways: (*a*) requires that an opening near the level of the ground be placed as close as convenient to the disconnecting trap on the house side as a fresh-air inlet, and describes how a ventilating pipe is to be carried up from the drain at a point as distant as possible from the first opening to a suitable height above the roof; and (*b*) defines that where this is impracticable inlet and outlet pipes in the reverse position to the last are to be adopted as an alternative. Paragraph 2 provides that a suitable grating or cover shall be fixed to these ventilating pipes, the openings in which shall equal the sectional area of the drain. Paragraph 3 settles that these ventilating pipes shall be of a sectional area not less than the drain with which they communicate. Paragraph 4 forbids the use of any bends or angles in these pipes unless unavoidable; and paragraph 5 allows the use of soil pipes or wastes of slop sinks as ventilators in place of the foregoing (By-law 6, paragraphs 1 and 2), provided they conform in all respects with the provisions already laid down and are of an internal diameter of not less than 3½ in., which shall be deemed sufficient for a 4 in. drain.

By-law 7.—Paragraph 1 prohibits the construction of any inlet to a drain within a building other than from a watercloset or slop-sink; paragraph 2 demands that all bath, sink, and lavatory wastes be suitably trapped immediately underneath and continued so as to discharge in the open air into or over a gulley, and if necessary be provided with an anti-syphonage pipe; and paragraph 3 points out that all safe-wastes and overflows of cisterns must deliver into the open air.

By-law 8.—Paragraph 1 deals with the soil-pipes both of new and old buildings. It reads: "Any person who shall provide a soil-pipe in connexion with a new building, or shall construct or refit a soil-pipe in connexion with an existing building," and directs that they shall be fixed outside if possible, and that they shall be of drawn lead if inside, adding directions as to joints and construction, and that the connexion with drain be made by means of a brass thimble. Paragraph 2 deals with the sizes, weight, and thickness of soil-pipes; paragraph 3 states that no rainwater-pipe shall be directly connected with the soil-pipe of any watercloset, and that no soil-pipe shall have a trap between it and the drain; paragraph 4 provides that they be not less than 3½ in. in diameter and be fixed free from bends if possible, and that they be open at the top, with a safe outlet for foul air; paragraphs 5, 6, 7, and 8 relate to various connexions between the several kinds of drains and soil pipes; and paragraph 9 stipulates as to the connexions of various kinds of closet traps and soil-pipes.

By-law 9 describes the anti-syphonage pipes for watercloset traps.

By-law 10, paragraph 1, provides for the proper trapping of slop sinks and prohibits the use of D-traps; and paragraph 2 treats of the size and weight of slop sink wastes, which wastes are not to be less than 3 in. in diameter and are to be provided with anti-syphonage pipes.

By-law 11 declares that the owner of any building shall maintain all pipes and drains in a proper state of repair.

By-law 12 decrees certain penalties for infringement of these by-laws.

By-law 13 is as follows: "These by-laws shall, so far as practicable, apply to any person who shall construct any pipe or drain or other means of communicating with sewers, or any trap or apparatus connected therewith, so far as he shall effect any such works in any building erected before the confirmation of these by-laws as if the same were being constructed in a building newly erected."

[1] The Report can be obtained from THE LANCET Office, 423, Strand, price 6*d*.

SUMMARY OF THE REPORT TO THE VESTRY OF ST. JAMES, WESTMINSTER, BY DR. EDMUNDS AND MR. MONSON, WITH OUR COMMENTARIES THEREON.

Dr. Edmunds and Mr. Monson report (*a*) that portions of the proposed by-laws are prolix and obscurely worded; (*b*) that some of the provisions are ambiguous and unintelligible; (*c*) that some of the requirements are unnecessary and oppressive; and (*d*) that in some points the requirements are inadequate. They also point out the importance of greater clearness and conciseness, and recommend that they be reconsidered, seeing that £40,000,000 sterling is the annual value of the rateable property affected by them.

In reviewing this criticism in detail, the suggestion (*a*) as to greater brevity and clearness is in several instances certainly very desirable. The objection (*b*) is also applicable to By-laws 8 and 13, where reference is made to other than new buildings. The next objection (*c*) is more open to question, as by a little less ambiguity in By-laws 8 and 13 many possible objections would be removed. Several of the by-laws, in every way desirable and reasonable when applied to new buildings, would possibly prove arbitrary and vexatious if enforced in an old one. Whether the term "so far as practicable" in By-law 13 is intended to leave some amount of discretionary power in the hands of local authorities is not quite clear; at all events, it should do so. It should not, however, be overlooked, that with any law made to benefit the many, it must happen that it will press heavily upon a few in some instances. Regarding objection (*d*) the suggestions given are: (1) That a by-law is required regulating traps; (2) that urinals should be assimilated to waterclosets and slop sinks; (3) that all cast-iron pipes for drains should be packed with yarn, jointed with molten lead, and properly caulked, also that old drains and filthy earth should be removed; (4) that drainage plans should be deposited by builders with the local authorities under penalty for neglect or falsification; and (5) that builders should fill drains with water and demonstrate the action of the drains under the direction of vestry officials when required. This last may be open to question.

To these might well be added:—(1) A specification of the number of tacks to be used on a soil pipe (an insufficient number is very frequently the cause of a fracture), say 6.8 lbs. cast lead tacks to each 10 ft. length; (2) that all bath or lavatory wastes being longer than 10 ft. should, in addition to the anti-syphonage pipe, be carried up to some convenient spot and left open at the top to ensure a free current of air through same; (3) that By-law 1 be made to include further provision as to ventilation—the subsoil drain under a house should at least be as well off in this respect as the soil drain that has to have sealed joints and is covered with concrete, seeing that they both communicate with a sewer, and with this drain there is the extra risk of the water in the trap becoming saturated with sewer air in dry weather.

By-law 1 has escaped criticism, though it would seem to be an elementary principle that an open-jointed drain passing under a house and ultimately connected with a sewer should not only be ventilated at the trap near the sewer, but that the extreme ends should be brought up just above the ground level and be left open to admit of a free current of air through them; also, instead of an air shaft by the trap, they should discharge over a gulley in an open area, if only as large as an ordinary manhole.

By-law 2, paragraph 2, regarding the exclusion of bath and sink or lavatory waste from rain-water heads, is considered by Dr. Edmunds and Mr. Monson as likely to be oppressive and unnecessary. Is not this criticism somewhat strained? The use of a large rain-water pipe for this purpose is often very objectionable, and with new buildings the use of any need not be necessary.

Regarding By-law 3, paragraph 1, exception is taken to the use of the word "communicating," which it is held is used in this and in By-laws 1 and 6 in varying senses. This criticism is difficult to follow. There is a great distinction to be drawn between communicating ultimately with a sewer and directly communicating. Is not this question rather of an academical than of a practical nature? The criticism of paragraph 3 defines more fully the composition of and the manner of forming the concrete bed, and these suggestions might be adopted with advantage. In criticising paragraphs 4 and 5 the report points out the difficulty frequently existing to the construction of a drain outside a building; though such a course may be possible, and suggests that this should be left optional to the local authorities. It also adds that in some buildings it is impossible to lay a drain in a direct line. The answer to this criticism is that in new buildings there should be no difficulty, if By-law 13 is rendered clear as to the meaning of the words "so far as practicable," there would be no difficulty in the case of old buildings either. The criticism of paragraph 9 suggests the substitution of the word "Mason's trap" for that of "dip-trap," on the grounds that the latter is ambiguous. This alteration would certainly improve the clause if Mason's trap is the one intended.

The criticism to By-law 5 proposes the addition that all branch drains should be provided with proper means of access.

In criticising By-law 6, paragraph 2, Dr. Edmunds and Mr. Monson propose that air inlets should be fitted with mica or other approved valves to prevent the reflux of air from the drain, and that the grating should stand vertical. Mica valves to fresh air inlets are a delusion and a snare. In a properly laid and ventilated drain foul air should be comparatively non-existent, and the small amount likely to issue from the air inlet, considering the situation, need not be thought of. Mica valves often become choked with dirt after a short time and are then worse than useless. The grating suggested should certainly stand vertically. In paragraph 3 they remark that the term "communicates" is here used obscurely, and question if it is intended where a 9 in. drain is used that a 9 in. ventilating pipe is to be used also. This criticism should undoubtedly be followed and the sense in which the word "communicate" is used made clear. The presumption is that it refers to the usual short branch drain with which the ventilating shaft is commonly connected. This view is corroborated by the reference to the use of the soil-pipe for this purpose in paragraph 5. Apart from the absurdity of a 9 in. ventilating pipe, it is difficult to imagine anyone using a 9 in. drain under these by-laws.

The criticism of By-law 7, paragraph 1, demurs to the prohibition of inlets to a drain within a building other than from a watercloset or slop sink, on the ground that in urban districts often the whole ground is covered. To this criticism it may be pointed out that with new buildings there can be no difficulty. For old ones provision is made in By-law 13. Gulleys in buildings frequently remain uncharged and manhole covers become loose with traffic.

The criticism of paragraph 2 of the same by-law is directed against the compulsory trapping of bath, lavatory, and sink wastes, and their being compelled to discharge over gulleys instead of rain-water heads and to the addition of anti-syphonage pipes. In reply to this it may be said that the by-law is to be preferred to the amendment: new buildings must not be allowed to offer any difficulties, and where there is any difficulty in old ones, owing to the want of proper fall in the waste pipes, the enforcement of this by-law is most essential, owing to the accumulation of dirty soap in them.

In criticising By-law 8, paragraph 1, the report most correctly proposes that the phrase "refit a soil pipe" needs further definition; in paragraph 3 it advises that the word "directly" be struck out, and approves of the word "connected" in preference to the word "communicate." In paragraph 4 it suggests that much of this might be struck out if all principal ventilating pipes were defined to have a minimum clear cross section of not less than nine square inches; and in paragraphs 5, 6, and 7, it is advisedly suggested that the words "to be approved of by the local authority" be added.

The criticism to By-law 11 questions the use of the word "owner," and would add "owner, lessee, and rated occupier," making all responsible to the local authority. This would undoubtedly be an advantage.

The criticism to By-law 13 maintains that this by-law is unintelligible, and would prevent improvements in old buildings for fear of bringing such under the operation of these new by-laws, and that no slight alteration could be made to any fittings without a liability of having to reconstruct the whole drainage system. It is proposed, with a view not to prevent gradual improvements, that the local authority should have discretionary power. As already remarked, this criticism points to a desirable alteration in rendering By-law 13 clearer upon the points raised.

ICHTHYOL IRRIGATIONS IN GONORRHŒA.

ONE of the newer methods of treating gonorrhœa is that proposed and carried out by Janet in 1892—viz., irrigation of the urethra with a solution of permanganate of potassium of the strength of a fifth of a grain to the ounce. This plan was subsequently practised in the St. George's Hospital at Hamburg, but without very satisfactory results; sometimes, indeed, very unpleasant effects were produced, such as painful œdema, hæmorrhage, and peri-urethral infiltrations. The Hamburg surgeons, however, have recently made further trials of Janet's irrigations, but with different solutions substituted for the permanganate. Ichthyol having been shown by Jadassohn to exert a very antagonistic effect to the multiplication of gonococci in mucous membrane, and having been favourably reported on by Canova of Paris as suitable for irrigating, was selected. The irrigator reservoir was a large glass vessel holding about four quarts. From this the fluid was conducted by an indiarubber tube, the lumen of which was sufficiently large to admit the thumb. At the other extremity was an ordinary urethral cone. A warm or cold 1 per cent. solution of ichthyol was used during the first five sittings, and afterwards this strength was doubled. The glass reservoir was placed on a stand, the height of which could be altered so as to exert as much hydrostatic pressure as might be required.

The most convenient position for the patient was found to be sitting on the edge of a stool, as in this position the resistance offered by the compressor urethræ and the sphincter appeared to be most easily overcome. In addition to the irrigations, which were carried out daily, the patient was directed to use a urethral syringe with a weak (½ per cent.) solution of ichthyol morning and evening, though but little was expected from this adjunct to the regular midday irrigations performed by the surgeon. These latter were carried out as follows. The patient, having first of all micturated, sits on the edge of a chair, leaning well back, and opening his legs. The terminal of the tube is now inserted into the urethra and the liquid allowed to enter so as to distend the passage. When this is accomplished and the dilatation can be felt by the surgeon's fingers the liquid is allowed to flow out, and will be found to be cloudy from flocculi and threads; and the douches must be repeated until the issuing liquid is quite clear. This generally takes ten or twelve ounces, and in this way the anterior portion of the urethra is effectually cleansed. A height of a little over three feet is sufficient for the reservoir during this part of the operation. If the posterior portion of the urethra is affected the reservoir is subsequently raised to about five feet above the patient's seat and the full force of the column of fluid obtained by compressing the meatus against the glass cone. In many cases the resistance of the compressor is overcome, especially when a little time is allowed, and the fluid passes into the bladder. Several ounces are thus introduced and the patient is then allowed to

Hosted by Google

micturate, care being taken once or twice during the flow to compress the urethra suddenly so as to obtain a better dilatation of its lumen.

Dr. Werner, writing in the *Monatshefte für Praktische Dermatologie* for August, gives an account of the results of this treatment in the 82 cases in which information was available. In 20 of these the disease was confined to the anterior portion of the urethra and had lasted for from a week to two months before the beginning of the treatment. Absolute cure was obtained in 19 cases with from 6 to 35 sittings (average 17). In 62 cases the posterior part of the urethra was also affected, and of these a cure was obtained in only 52, the number of sittings required being from 2 to 40 (average 19). The single unsuccessful case of anterior urethritis was one of a month's duration. Here, however, the gonococci disappeared after 28 douches, but as the catarrh continued the cure could not be said to be complete. It was, however, quickly effected by zinc sulphate injections. Of the 9 cases where cure was not obtained some left the hospital against advice before a cure could be effected, and in some epididymitis supervened which obliged the douches to be discontinued. In three of them, however, the gonococci had entirely disappeared after from 3 to 28 douches. Several cases of gonorrhœal cystitis, some of them with pyrexia and severe tenesmus, were very successfully treated by ichthyol douches, but in some others no effect was produced and the cure was obtained by argonin. A number of cases were treated by means of douches of resorcin of the strength of 1 per cent. applied similarly to the ichthyol irrigations, but with very much less satisfactory results. As evidence of absolute cure Dr. Werner requires the following facts: (1) that after twenty-four hours' cessation from treatment no visible discharge is present; (2) that the urine when poured from one vessel into another is free from threads; and (3) that no gonococci can be detected in the last gonorrhœal threads found. Strictly speaking, of course, further examination should be made later, but this is impracticable with hospital out-patients.

A NOTEWORTHY INQUEST.

AN inquest has recently been held at Bushey which presented many features of peculiar interest. The deceased, a woman who had died in childbirth, had arranged to be attended during her confinement by a midwife. At 6 A.M. on the morning of March 29th hæmorrhage came on. The midwife was summoned and arrived at 7.50 A.M. What followed can be learned from her deposition:—

Alice Mary Jennings, a midwife, states: "I saw the deceased woman first about 7.45 on Monday morning, March 29th. I then examined her and found that she had then lost between three and four quarts of blood, so far as I can judge. I was told that she had had a fainting attack. She was on the bed, and I found that the head was presenting with the face, and that the placenta was partially presenting. The head of the child had not entered the pelvis, the os uteri was rather larger than half-a-crown, and the cervix was not entirely shortened. There was not much bleeding going on. I plugged the os lightly with a soft silk handkerchief. I did not attempt to sterilise the handkerchief in any way, but I used a solution of 1 in 500 of corrosive sublimate for washing my hands. I did not use any vaginal douche. When the os was dilated, something after nine o'clock, I ruptured the membranes and separated the placenta as far as I could reach it, and brought down one foot at first, and after that there was little or no further loss of blood. The labour pains were very few and ineffective. I brought down the other foot about 11.30, and the child was finally born at 12.30. I administered one dose of quinine, fifteen grains. When I first plugged the os I gave fifteen grains of chloral. I gave her also one ounce of cane sugar. Neither the quinine nor the sugar had any effect on the pains. After the expulsion of the placenta I gave her a douche of iodine, about a teaspoonful of a mixture of equal parts of the tincture and the liniment of iodine. I gave her two and a half grains of ergotin in tabloid form. The woman seemed fairly comfortable. Her pulse was beating 120 to the minute, it was weak, and was like a pulse which I expect after hæmorrhage. I stayed about one hour and a quarter after the child was born. The uterus when I left was well contracted. The pulse had improved, and she wished to go to sleep. I left about 1.45. She had been taking nourishment very freely all the morning. I gave egg, milk, tea, and no stimulant. About 3 o'clock her husband came for me, saying that she was in violent pain, but by the time I arrived the pain had ceased, the uterus was still well contracted, and there had been no further severe loss of blood. She was looking very ill, her pulse was very rapid, and she complained of feeling faint. I administered about three-quarters of a teaspoonful of sal volatile, and I injected by the rectum three pints of saline mixture. She seemed much better and said she felt more comfortable, but from time to time she said that she felt faint. I administered brandy and sal volatile, bovril, and about 4.30 I noticed her breathing change very much. I then sent for a doctor and I injected ether hypodermically—rather over a drachm in all—but before I had finished injecting the ether the patient was dead. If I had thought it necessary I should have sent for a doctor earlier, but I did not think it necessary considering the condition of the woman. I think now, after the event, that I should have sent earlier for a doctor. I hold a certificate from the British Lying-in Hospital and I hold the Obstetrical Society's diploma. This is one of the cases in which I was taught to send for a doctor immediately."

A post-mortem examination was made by Mr. Arthur Stradling of Watford, who examined the body of the deceased about thirty-two hours after death.

"I examined the heart," he deposed, "and found a clot in the pulmonary artery, the right side of the heart being empty. There was no sign of previous disease in any organ. The uterus was relaxed, somewhat pallid; the appendages normal. The site of the placenta was at the fundus It was empty. There were no signs of any recent operation, nor were there any tears or laceration in any part of the genital tract. I formed the conclusion that death was caused by the clot in the pulmonary artery. There was no sign of the placenta being prævia. I was informed by the nurse that there had been no hæmorrhage previous to the commencement of labour. The body was not actually drained of blood."

At this point the inquest was adjourned until April 7th, when nine medical men appeared to testify to the correctness of the conduct of the case by the midwife. The court was then cleared and the coroner, Dr. Lovell Drage, summed up as follows:—

"The first duty of the jury in an enquiry such as this is is to find the actual cause of death. The evidence provides, in the case of the unfortunate woman of whose body you have had the view, conclusive evidence upon this point, to the effect that it was caused by pulmonary embolism subsequent to ante-partum hæmorrhage, and I charge you to this effect. The second duty is to consider the circumstances of death. The hæmorrhage, which undoubtedly was at the root of the question of the cause of death, occurred before the midwife responsible for the care of the deceased woman arrived. She therefore was in no way responsible for it. But the question arises, given the hæmorrhage at the commencement of labour, is it reasonably probable that the condition which subsequently produced death might have been prevented if skilled assistance had been promptly obtained? I must remind you that the midwife admits in her evidence that during her training she was taught that this was one of the cases in which she must summon a medical man. If she was so taught there can be no reason to doubt that the condition is one well recognised as being fraught with danger to the patient. This question of probability is one of great difficulty, and I urge you to follow closely what I have to say to you. The conditions which favour the formation of such a clot as that which caused this death are three—those peculiar to all pregnant and lying-in women, those the result of hæmorrhage, and those the result of the disease. The two former were present in this case. The deceased woman on the arrival of the midwife had already had a fainting fit, and from the evidence the hæmorrhage must have been a large one. In such a case it was the plain duty of the person responsible to do what was necessary to restore the circulation and to terminate the labour as soon as was practicable. I must remind you that the condition which actually caused death is one which arises under a variety of circumstances, and you must consider carefully whether you should look upon the fatal result as one which was probable in the case of a young healthy woman if skilled assistance had been procured early. Accidents occur, no doubt, in all hands, and, with my experience of midwifery, no one is more alive to this than I am. If you are satisfied that a fairly reasonable treatment was adopted you must come to the conclusion that accident was the cause of that fatal condition. If you are not so satisfied you must carefully weigh the probability of that fatal condition being the result of causes which were not controllable by human agencies and the probability of its being the result of the neglect of measures which might have been adopted and which might have saved life. Death from pulmonary embolism may undoubtedly occur in any woman after delivery, but it is a rare cause. In an experience of about 1200 cases of delivery in private practice I have only known one, and in a hospital experience of about 800 I cannot recollect any. So far as my experience shows it has occurred once in about 2000 cases, and in that case I was not summoned until after delivery was completed."

The following verdict was then given:—

"That the said Adelaide Emily Whiteley died on March 29th from pulmonary embolism, subsequent to ante-partum hæmorrhage. That the midwife is much to blame—(1) for not calling in a doctor when she found at 8 o'clock in the morning the very serious condition of her patient; (2) for not acquainting the husband with that serious condition; (3) for exceeding her duties as a midwife, contrary to the rules of the Obstetrical Society, and in the absence of a medical man."

The verdict is an exceedingly serious one for the midwife. With her actual procedure from a medical point of view we are bound to be satisfied, as it would seem that no less than nine medical men testified to the correctness of her conduct of the case. Her diagnosis of a placenta prævia, however, was directly challenged by medical evidence, so that by analogous reasoning she would seem here to have been in error. But we are not disposed to blame her or add to her grief at the loss of her patient by laying much stress on this failure to comprehend the pathology of the case. Such knowledge was not to be expected of her. Where she went wrong was in assuming responsibilities which she was unequal to meet, and the jury could not have pointed this out to her in more firm and uncompromising terms.

THE NEW WATER-SUPPLY AT WORTHING.

THERE is no more important event in the history of a town than the inauguration of a pure and plentiful water-supply, and nowhere can there be a subject for warmer congratulation than the completion of the new waterworks undertakings at Worthing. The Council have been beset with all kinds of difficulties and obstacles ever since they have gallantly endeavoured to replace the old and condemned source of supply. The problem has at length been successfully solved, and the authorities are to be highly commended on the excellent spirit and energy they have shown in their anxiety to free the town from so unenviable a subject of reproach as its water-supply. On Monday next, the 26th inst., the new works are to be formally opened by His Royal Highness the Duke of Cambridge, and the occasion is one upon which the inhabitants of Worthing may well rejoice.

The water is drawn from a well at the foot of the South Downs. The new works which are to replace the temporary provision were commenced some two years ago, but several unavoidable delays have occurred. They are situated about two miles north of the town, and with the pumping station and reservoir cover about three and a half acres of ground, the reservoir standing further northward on the chalk soil itself, the excavation for that purpose amounting to no less than 12,000 loads. The capacity of the reservoir is about 2,000,000 gallons, which should serve as an ample stock for daily supply, the requirements being on the average about 750,000 gallons per day. The walls are very solidly built, being constructed of layers of concrete asphalt and very hard brick. The engines to be used alternately are each of about 87 horse power, and each engine and set of pumps is capable of raising a thousand gallons of water a minute to a height of 215 ft. Every possible precaution has been taken to secure the water in the well against contamination. The shaft of 119 ft. is cased with flanged iron shields in segments, the joints being made of pitch pine vertically and of yarn and Russian tallow horizontally, headings having been provided to increase the supply 150 ft. in length, 6 ft. high, and 4 ft. wide.

At our request the Mayor (Captain A. B. S. Fraser) was good enough to forward us a sample of water taken from the reservoir, which we have duly submitted to analysis and examination in THE LANCET Laboratory. The water was contained in a clean, stoppered, clear glass Winchester quart bottle. The stopper was tied down with leather and secured with string properly sealed. A tag tied to the neck had the following written upon it: "From the Mayor, A. B. S. Fraser, 14/4/97; countersigned W. H. P. Fletcher, chairman of Sanitary Committee of Worthing." The label upon the side of the bottle bore the following words: "Water from Reservoir, Worthing New Permanent Waterworks, taken at 7 A.M. Thursday, April 15th, 1897. Frank Roberts, Borough Surveyor; Chas. T. Gardner, Sanitary Inspector." The results of our analysis together with other observations are as follows:—

Analysis of Worthing Water taken from New Reservoir.

Appearance	Bright and clear.
Colour	Slight greenish tint.
Smell	None.
Total solids	19·60 grains per gallon.
Loss on ignition	1·40 " " "
Change on ignition	Slight, no charring.
Temporary hardness	12·52 grains per gallon.
Permanent hardness	4·00 " " "
Chlorine in chlorides	1·82 " " " (equal to common salt, 3·00 grains per gallon).
Nitrogen in nitrates	0·35 grains per gallon.
Nitrogen in nitrites	None.
Free ammonia	None.
Albuminoid ammonia	0·0056 grains per gallon.
Oxygen absorbed	0·02 " " "
Phosphates	No trace.

These results are in perfect accordance with those obtained with water of the well-known purity and character furnished from the chalk. Considering the results as a whole, there is not the slightest indication of contamination with objectionable organic matters. This is particularly evident from the fact that the water was absolutely free from free ammonia, contained no nitrites, and no trace of phosphates, while the solids on ignition yielded no smell or other evidence of organic matter present. The chlorides, again, are typical of pure natural water, and the factor "oxygen absorbed" is so low as to show that the water is quite free from oxidisable substances. Since the water is well aerated it would be a matter of surprise to obtain any other result. Again, the amount of nitrates is distinct and in a quantity characteristic of waters that have met with the great purifying processes of nature. The sample was bright and clear, possessed no smell, and exhibited a slight greenish tint when viewed in deep column. As might be expected, it is somewhat hard, the total hardness being 16·52°, of which 12·52° are removable on boiling.

We congratulate Worthing on at last possessing such an evidently pure and abundant supply of water that proves to be excellent for all dietetic purposes, and we trust that the inhabitants have heard for the last time of the troubles contingent upon the pollution of life's first necessity. The authorities have worked unremittingly towards securing a satisfactory solution of what has proved a difficult problem, and they have not been neglectful to learn and profit by one of the first lessons in sanitation. The experience has been a bitter one, but it has led to an eminently satisfactory issue, and confidence in the future being restored there is no reason why it should not be permanent. We propose to examine further samples from time to time in THE LANCET Laboratory, both chemically and biologically, and to publish the results. It will be interesting to see if the composition of the water undergoes any variation, whether taken from the source, reservoir, or service pipes.

THE FINANCIAL CONDITION AND REQUIREMENTS OF THE UNIVERSITY OF CAMBRIDGE.

WE have received from the Chancellor of the University of Cambridge (the Duke of Devonshire, K.G.) a statement concerning the present financial condition of that University and its future pecuniary outlook, which cannot fail to strike our readers, as it strikes us, as one of the deepest importance. Space will not permit us to do more than summarise the statement, which, it should be added, is authoritative, if not official, being the outcome of a recent meeting to which all the principal officers of the University and representatives of the several colleges were invited. In his Grace's words, it may therefore be considered as "made on behalf of a very large number of those who are conducting the practical educational work of the University."

The statement commences by pointing out that the common assumption that the University of Cambridge is a very wealthy body is not justified or justifiable. On the contrary the fall in agricultural value has seriously diminished the available income of the University and its constituent colleges, while the expenditure necessary to provide for the maintenance of the several branches of instruction and research has steadily increased. Benefactions for general academic purposes have also practically ceased, although many munificent donations have been made for the founding of special prizes.

The expenditure of the University in 1896 was as follows:—

Stipends of officers, professors, readers, University lecturers, demonstrators, examiners, &c.	£33,229
Maintenance of establishments, repairs, rates, wages, &c.	22,057
Instalment in repayment of building loan (£40,000)	2,256
Part of the payment for purchase of building sites	5,000
Total	£62,542

The stipends to be paid number 120, and speaking generally the services rendered amount to tuition in all the higher branches of literary, philosophical, and mathematical subjects, as well as all the various departments of natural science. The stipends are partly met by College Fellowships as the present statutes direct that a professor who is also a Fellow of a hall have his stipend diminished by £200 per annum

Hosted by Google

in consideration of his College dividend. College dividends in nearly every instance fall below £200; this means that in many cases the total stipend falls below its nominal amount. The establishments to be maintained comprise the University Library and certain Special Libraries, the Divinity and Literary Schools, the Observatory, the Botanic Garden, eight Museums, and eight Laboratories.

The general revenue for 1896 was thus made up:—

Capitation Tax and fees for matriculations, examinations, degrees, &c.	...£39,366
College Contributions (net.)	... 16,577
Endowments (net.):—	
(*a*) For special purposes	... 5,850
(*b*) Not specially appropriated ...	... 844
Total	£62,637

With regard to the revenue we learn that the Capitation Tax on undergraduates has recently been more than doubled, and that many of the Degree Fees have been raised; that the College Contributions owing to long continued agricultural depression have not ensured to the University the large and expanding income that the Commissioners under the Universities Act of 1877 had anticipated; and, lastly, that the insignificant amount received from Endowments being largely derived from tithe and agricultural rents, has decreased and will decrease still more.

This is the financial position of Cambridge University, exposed by the statement that we have received from the Duke of Devonshire at a time when the number of students in the University is just double what it was in the last generation, and when ample accommodation and equipment in all the departments of learning are urgently required. A number of important branches of study are unrepresented by professorships. There are serious requirements involving capital expenditure, of which the following are specified:—the space occupied by the University Library must be considerably extended; a building must be provided for a School of Law; University lecture-rooms, offices, and examination-rooms are all needed, the present accommodation being totally inadequate; the buildings assigned to the departments of botany, zoology, and pathology are over-crowded and inconvenient; and a suitable museum is necessary for the proper display of the antiquarian and ethnological collections of the University.

"It will thus be seen," the statement concludes, "that while the resources of the University are essentially inexpansive, the reasonable demands upon it for further large expenditure are urgent and increasing. To meet these in the manner contemplated by the Commissioners of 1877 and expected by the nation at the present day, the re-endowment of the University in respect of many of its departments is a pressing necessity."

THE GRECO-TURKISH WAR.

ALTHOUGH it is well known that Turkish troops always form a formidable force to deal with, and that the Turkish soldier is very brave and resolute in battle and what Rudyard Kipling terms a "fust-class fighting man," it was generally believed that, owing to their weak and effete military system, the Turkish army was not well led, well fed, or properly cared for. The accounts that have been published regarding the condition of preparedness of Turkey for war, and of their medical service and field hospital organisation, are consequently calculated to awaken surprise. The Turks, as a Mahommedan Power holding the doctrine of fatalism as an article of their religious faith, have not hitherto been remarkable for the care they have taken of the sick and wounded. But they have apparently learned as a matter of experience the necessity of having a well-organised medical system and properly equipped hospitals for field service, and their advances in this respect have been great if we may judge from the accounts that have appeared as to the efficient and comfortable state of their hospitals in the present war. The excellence of their hospital organisation and arrangements have been more than once adverted to by the special correspondent of the *Times*. Ahmed Pasha is the chief of the medical service at Elassona, and he has lately accepted the offer of medical assistance made by Sir E. Vincent. No accounts have been published of the state of the Greek medical service and hospital organisation for war, although it is well known that great efforts have been made of late in this direction, with what results we shall probably soon learn. The Greeks have, as we know—for several nurses have gone from this country—organised a system of female nursing for their hospitals, and ladies of the Royal family and others have been taking an active part in this and other matters connected with the present war. According to a telegram that appeared in the *Daily News* the preparations still leave something to be desired in the way of surgical and medical stores, such as disinfectants, lint, bandages, &c., for the Hellenic hospitals. The Greeks have sent out two hospital ships to Volo to take off the wounded. The steamer *Thessaly* has been converted into a floating hospital with 300 beds for this purpose, on the initiative of the ladies of Athens and under the patronage of the Queen of Greece.

The accounts from the scene of warfare are somewhat conflicting and difficult to understand. As might be expected, they vary very much according to the source whence they are derived. But there does not appear to be any doubt that the Turks have captured the whole of the Maluna Pass and driven their Greek enemy across the frontier towards the plains of Thessaly, where a big and decisive battle may be expected to follow. Strategically considered, the military importance of this achievement seems undoubted, for the possession of this pass directly opens up the way to Larissa, the headquarters of the Greek force. At Reveni, however, one of the principal entrances into Thessaly, and in some other directions the Greeks claim to have gained great advantages.

The very difficult and mountainous nature of the country where the fighting has hitherto taken place has been opposed to the occurrence of any close and decisive engagement between large masses of troops; and the clearing of the ground and hill sides of the wounded must have been a matter of much difficulty, requiring an ample provision of ambulance transport in order to render timely aid and succour to the wounded of both belligerents, during the severe fighting which has taken place. All accounts agree that there has been great determination and valour displayed on both sides in attacking and defending important positions. It is still possible that, as the fighting is on such extended lines, the war, which looks as if it were too acute to last long, may nevertheless be more protracted than is generally thought, unless some decisive battle on a large scale soon takes place. At the present moment the Turks seem to be the masters of the situation. The object of the European Powers will be, of course, to confine the warlike operations to the belligerents now engaged and prevent, if possible, a general conflagration in the East, the disastrous consequences and ultimate results of which no one could foretell. In the meantime there will, it seems to us, be ample opportunity for the work of volunteer aid and International Red Cross societies to provide hospital and surgical succour for the sick and wounded—Christians and Mohammedans alike.

THE TWELFTH INTERNATIONAL MEDICAL CONGRESS.

THE ROUTES TO MOSCOW AND THE EXPENSES OF TRAVELLING.

THE English Committee acting for the organisation of the Twelfth International Medical Congress to be held in Moscow from Aug. 19th to Aug. 26th inclusive have mapped out a choice of routes by which Englishmen desirous of attending the Congress may proceed to the Russian capital. We propose here to sketch in outline the principal ones—that is to say, those which are most convenient, most direct, and least expensive. It will, of course, be open for individuals to vary the journey by breaking it at interesting places or by going rather off the direct line in order to visit other places of interest. We shall probably, however, not be very far wrong in presuming that most practitioners will prefer to proceed direct to Moscow in time for the opening of the Congress, and that those who wish to break or vary the journey will do so on their way back rather than on the outward journey. The present statement will, therefore, be confined to the most direct routes to Moscow only.

Hosted by Google

The following five skeleton routes fall into two groups. By the first two routes, A and B, the journey is an overland one, by rail the whole way; by the remainder the journey is, for the most part, by sea, the time spent in a railway train being reduced to a comparatively few hours.

Route A.—Overland to Moscow, *viâ* Flushing, Berlin, and Warsaw. Approximate time of journey 84 hours. Leave Victoria (say) Saturday, Aug. 14th, 8 30 P.M. Night crossing Queenborough to Flushing. Leave Flushing 5 5 A.M.; arrive Berlin 7 P.M. Sunday. Leave 11 P.M; arrive Alexandrovo (Russian frontier) 7 A.M. Monday. Leave 8 21 A.M; arrive Warsaw 2.32 P.M. Leave 4 5 P.M.; arrive Moscow 8 30 A.M. Wednesday morning, Aug. 18th. The Congress will commence on Aug. 19th. Fares: London to Berlin, £4 3*s.* 9*d.* first class; £2 18*s.* 10*d.* second class. Berlin to Moscow, £4 17*s.* 6*d.* first class; £3 5*s.* second class. Sleeping cars: Berlin to Alexandrovo, 10*s.* 6*d.* first class, 7*s.* second class; Warsaw to Moscow, 18*s.* first class; 16*s.* second class. A return ticket lasting thirty days can be taken from London to Berlin, costing £5 19*s.* first class and £4 3*s.* 5*d.* second class. This route has the great advantage of speed. It will be possible to leave London at 8.30 P.M. on Sunday night, Aug. 15th, and arrive in Moscow early on Thursday morning, the opening day of the Congress. By leaving a day or two earlier the journey might be broken at Berlin, Warsaw, or Smolensk. A branch committee of the Congress has been formed at Smolensk to facilitate the journey for foreigners. The total cost by this route, including sleeping cars, is as follows: Single fares, £10 9*s.* 9*d.* first class; £7 5*s* 10*d.* second class. Return fares, £18 11*s.* first class; £12 7*s.* 1*d.* second class. The living on Russian railways is good and cheap. The fares here given as return fares are obtained by doubling the fares beyond Berlin and adding the return fare to Berlin; return tickets on the Russian lines would probably be less. Messrs. Cook and Son (Chief Office, Ludgate-circus) undertake to supply through tickets if applied for six days in advance; otherwise it is necessary to book to Berlin and re-book from there to Moscow. The travelling expenses by this route, it will be noted, will not exceed £20, to which another £4 may be added for meals, &c., while travelling. The cost of staying in Moscow will depend on whether the traveller stays at an hotel or is entertained by an English family. In any case, the whole trip by this route need not cost more than from £30 to £35, first class both ways; by travelling second class the expenses will be some £6 less. Both the German and Russian lines have comfortable second-class carriages. The sleeping cars are practically the same for both classes. There is some probability that the fares on the Russian lines will be reduced for members of the Congress.

Route B.—Overland to Moscow, *viâ* Flushing, Berlin, and St. Petersburg. Approximate time the same as Route A. Route to Berlin as above. Leave Berlin 11 P.M. Sunday; arrive Wirballen (Russian frontier) 12.9 noon Monday; leave 2.4 P.M.; arrive St. Petersburg 10.45 A.M. Tuesday. Proceed to Moscow the same night or the following night. It is necessary to drive across St. Petersburg from the station of arrival to the Nicolas Station (Nicolaiefski Volksaal). Trains at 3 P.M., arriving at Moscow 8 10 A.M. next day (slow but cheaper) and at 9 P.M., reaching Moscow 10 10 A.M. (faster but more expensive). Fares: London to Berlin as in Route A; Berlin to Moscow, £6 9*s.* first class, £4 8*s.* 6*d.* second class. Sleeping cars, Berlin to Wirballen, 12*s.* 6*d.* first class, 10*s* 6*d.* second class; Wirballen to St. Petersburg, £1 5*s.* first class, £1 1*s.* second class. (The fares on this line vary slightly with the train selected.) This route has the same advantage of speed as the last. It will be possible to leave London on Sunday evening, arrive in St. Petersburg before 11 A.M. on Wednesday, and proceed to Moscow that night. The fares on the Russian lines will probably be reduced for members of the Congress The total cost of travelling by this route will be from £25 to £30 first class, including the cost of living on the journey; or from £20 to £25 second class. There is a *train de luxe du Nord* which starts from Charing-cross and Victoria at 10 A.M. every Saturday (*viâ* Ostend); the single fare to St. Petersburg by this train is £15 4*s.* 6*d.* A similar express train leaves Charing-cross and Victoria at 11 A.M. every Saturday for the Dover-Calais route *viâ* Brussels and Cologne to Berlin. The fare to St. Petersburg by this route is 10*s.* 3*d.* more than *viâ* Ostend. The journey by either route is completed in 52 hours; St. Petersburg is reached on Monday at 3.50 P.M. (Russian time). These trains have dining-cars attached.

Route C.—Direct by sea from London or Hull to St. Petersburg, and by train thence to Moscow. Two English lines of steamers run to St. Petersburg, the Wilson line and the Bailey and Leetham line. The Wilson steamers (London agents, W. E. Bott and Co., 1, East India-avenue, E.C., who will give detailed information of the sailings later) sail every Saturday from Hull, and reach St. Petersburg usually on the following Friday or Saturday. Occasionally in the summer a steamer sails in addition in the middle of the week. The steamers have accommodation for between fifteen and thirty first-class passengers. They do not, as a rule, call at any intermediate port, but the voyage is far from monotonous, the scenery in the Cattegat and Sound and in the Gulf of Finland being exceedingly picturesque. Fares: £5 5*s.* single; £7 17*s.* 6*d.* return (available by any steamer during the season). The charge for meals is 6*s.* 6*d.* a day, exclusive of liquors. The Bailey and Leetham steamers (London address, 12, Mark-lane, E.C.) sail from London every week or ten days; the days of sailing are not fixed. The fares and charges for meals are the same as on the Wilson steamers. From St. Petersburg to Moscow, for trains, see previous routes. The fares are about £2 first class, and £1 5*s.* second class, including sleeping car, but vary slightly with the train selected. The total cost, going and returning by this route, would be as follows:—

Return fare on steamer	£7	17	6
Stewards' fees	1	0	0
Fares to and from Moscow, first class	4	0	0
(If second class only £2 10*s.*)			
Total	£12	17	6

The actual travelling expenses are thus reduced to £12 17*s.* 6*d.*, or with a liberal margin for extras, £14. Living on board is cheap, the charge, as stated above, being 6*s.* 6*d.* a day; twelve days (out and home) at this rate would cost £3 18*s.* The charges at the buffets on the railway are also cheap, so that the essential expenses of the trip would be less than £20. If, as is hoped, the English members of the Congress are to be hospitably accommodated by the English colony in Moscow the additional expenses need be very slight. If, on the other hand, the visitor should stay at an hotel for eight days in Moscow and two or three days in St. Petersburg his additional expenses need not exceed £10, and will probably be less. In this way the whole trip, for which four weeks should be allowed, will cost from £25 to £30. For this sum the trip may be accomplished in ease and comfort. Since the Congress is to be opened on Thursday, Aug. 19th, it will be necessary to sail on Saturday, the 7th, if this route is chosen. The spare three or four days could be spent in St. Petersburg. Should an extra steamer, as sometimes happens, be despatched, say, on Wednesday, Aug. 11th, it would enable passengers to arrive in Moscow on the morning of Thursday, the 19th, the opening day of the Congress.

Route D.—By sea from Hull to St. Petersburg direct, or by sea from Hull to Helsingfors; thence by train to St. Petersburg and Moscow. A Finnish line of steamers (London agents, Chas. Gee and Co, 17, Gracechurch-street, E.C.) sends a boat from Hull every Saturday. The steamer reaches Hango the following Wednesday, and Helsingfors the following Thursday. Trains leave Helsingfors 8.50 A.M., reaching St. Petersburg 10 40 P.M.; and 8.15 P.M., reaching St. Petersburg 9.40 A.M. Trains also go from Hango to St. Petersburg. Fares to members: Hull to St. Petersburg, £4 8*s*; Hull to Helsingfors, £3 15*s.* Charge for meals 5*s.* a day. Fares from Helsingfors to St. Petersburg about £1. Trains and fares from St. Petersburg to Moscow as in previous routes. Members of the Congress who wish to be in time for the opening day would have to leave Hull on Saturday, Aug. 7th, reaching Helsingfors on Thursday, the 12th; this would allow a week to visit places of interest in Finland and to proceed at leisure to St. Petersburg and Moscow. Total cost by this route, Hull to Moscow, £8; return, £14; meals extra. This is one of the cheapest routes. The boats are comfortable and have electric light throughout; the cuisine is Swedish. There is a stop of several hours in Copenhagen, enabling passengers to land and see the city. Helsingfors, the Finnish capital, is also well worth seeing.

Route E.—By sea from London, Hull, or Grimsby to Gothenburg; thence by train or canal to Stockholm; thence by sea to St. Petersburg; thence by rail to Moscow. The s.s. *Thule* or s.s. *Thorsten* (London agents, W. E. Bott and Co., East India-avenue, E.C.) leaves London every Friday morning; voyage to Gothenburg about three days.

Hosted by Google

The journey from Gothenburg to Stockholm may be done by rail in twelve hours; by canal, passing some of the most beautiful scenery in Sweden, in about two days. Canal steamers sail almost daily. Steamers leave Stockholm for St. Petersburg three times a week; the voyage takes two and a half days. These steamers call at Abo, Hango, and Helsingfors, and are exposed to the open sea for only a short distance. The Wilson Line sends a steamer from Hull to Gothenburg every Saturday after 5 P.M., and one from Grimsby to Gothenburg every Thursday at noon. From Gothenburg the journey would be continued as above. Fares: London to Gothenburg, £3 3*s.* single, £5 5*s.* return, available during the season. Hull or Grimsby to Gothenburg the same. Living on board in all cases 6*s.* 6*d.* a day. Gothenburg to Stockholm, by rail £1 9*s.* 6*d.* second class, by canal £2 8*s.* 4*d.*, including food. Stockholm to St. Petersburg by sea, to members, £1 16*s.* St. Petersburg to Moscow, *vide* previous routes. The time taken by this route would be as follows:—

By sea to Gothenburg about...	3 days.
Gothenburg to Stockholm by rail or canal...	½ or 2 days.
Stockholm to St. Petersburg	2½ days.
St. Petersburg to Moscow	1 day.
	7 or 8½ days.

To reach Moscow in time for the opening of the Congress it would be necessary to sail from London on Friday, Aug. 6th, or from Hull on Saturday, Aug. 7th, as the following week's sailing would be too late. But it would be just possible to sail from Grimsby on Thursday, Aug. 12th, and, crossing Sweden by rail, to reach Moscow on the morning of Thursday, the 19th, the opening day of the Congress. The total cost by this route would be as follows:—

	£	*s.*	*d.*
Return fare to Gothenburg	5	5	0
Gothenburg to Stockholm and back (second class)	2	1	0
Stockholm to St. Petersburg and back...	3	12	0
St. Petersburg to Moscow and back (first class)	4	0	0
	£14	18	0

Meals for fifteen days' travelling (mostly at 6*s.* 6*d.* a day), say, £5. This will bring the total travelling expenses, going and returning by this route, to between £20 and £25. Add £10 (if the visitor stays at an hotel), and the total expenses amount to between £30 and £35. It would be considerably cheaper to go this way and return direct by sea, or *vice versâ*. Passengers by this route have an opportunity of seeing Gothenburg, Stockholm, Abo, Hango, and Helsingfors, in addition to St. Petersburg and Moscow. Tickets for all routes to Berlin, or all sea routes to St. Petersburg, are issued at any of Messrs. Cook and Son's offices.

Messrs. Thomas Cook and Son have arranged to conduct a party to Moscow at an inclusive rate. The outline of the trip they propose shows that a start will be made from Queenborough for Flushing at 8.30 P.M. on Thursday, Aug. 12th, and that Berlin will be reached on the following day, Warsaw on the morning of the 16th, and Moscow at 2.15 P.M. on the 18th. The return journey, commencing Friday, Aug. 27th, will be by St. Petersburg, Stockholm, Copenhagen, and Hamburg, and London will be reached at 7.50 A.M. on Thursday, Dec. 9th. The fare, which covers railway tickets, hotel accommodation, and conveyance of baggage (56 lb.), is 45 guineas. Messrs. Cook and Son offer an alternative return journey by Berlin and Hanover for which the inclusive fare is only 38 guineas.

Dr. Lunn, 5, Endsleigh-gardens, N.W., has arranged a twenty-eight days' cruise for 25 guineas, exclusive of the cost of living and travelling in Russia. A start will be made in the steam-yacht *Norse King* at 6 P.M. on Tuesday, Aug. 10th. from Newcastle, and St. Petersburg will be reached on Aug. 17th. The yacht will then wait at St. Petersburg, and the return journey will commence on Aug. 27th; Stockholm will be reached on Aug. 29th, Copenhagen on Sept. 3rd, Christiania on Sept. 5th, and Newcastle on Sept. 8th.

An account of the excursion organised by the executive committee of the Congress to visit the Caucasus will be found in THE LANCET of April 3rd, 1897, p. 974.

Whatever route be chosen the intending traveller must obtain a passport from the Foreign Office, and see that it is properly *visé* at the Russian Consulate, 17, Great Winchester-street, E.C. If he is going through Germany he had better get the German *visa* too.

Notice has been received from Professor W. K. Roth, Secretary-General of the Congress, of important reductions in railway fares that will be made to members of the Congress. French, Spanish, and Norwegian railways announce a reduction in fares of 50 per cent. The Italian railways offer a reduction varying from 30 to 50 per cent. The Hungarian railways will convey a member of Congress by a class superior to that for which he holds a ticket. Lastly, *free* return tickets will be given by the Russian railways from the frontier to Moscow and back.

Forms of inscription as Member of the Congress can be obtained from Mr. G. H. Makins, 47, Charles-street, Berkeley-square, London, W.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 5754 births and 3764 deaths were registered during the week ending April 17th. The annual rate of mortality in these towns, which had been 18·3 and 18·6 per 1000 in the two preceding weeks, declined again last week to 17·9. In London the rate was 16·6 per 1000, while it averaged 18·7 in the thirty-two provincial towns. The lowest rates in these towns were 9·5 in Croydon, 10·9 in Swansea, 11·9 in Nottingham, and 13·1 in Wolverhampton; the highest rates were 23·3 in Manchester, 23·4 in Halifax, 24·9 in Bolton, 25·8 in Blackburn, and 28·1 in Salford. The 3764 deaths included 335 which were referred to the principal zymotic diseases, against 346 and 338 in the two preceding weeks; of these, 105 resulted from measles, 100 from whooping-cough, 51 from diphtheria, 33 from scarlet fever, 30 from diarrhœa, 16 from "fever" (principally enteric), and not one from small-pox. No death from any of these diseases was recorded last week in Swansea; in the other towns they caused the lowest death-rates in Bradford, Croydon, Nottingham, and Sunderland, and the highest rates in Oldham, Liverpool, Blackburn, Salford, and Bolton The greatest mortality from measles occurred in Bolton, Manchester, Salford, Oldham, Burnley, and Newcastle-upon-Tyne; from scarlet fever in Leicester; and from whooping-cough in Leicester, Manchester, Salford, Burnley, Preston, Blackburn, and Gateshead. The mortality from "fever" showed no marked excess in any of the large towns. The 51 deaths from diphtheria included 30 in London, 3 in West Ham, and 2 each in Birmingham, Liverpool, Manchester, Leeds, and Sheffield. No fatal case of small-pox was registered during the week under notice either in London or in any other of the thirty-three large towns. There were 11 cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, the 17th inst., against 21, 17, and 16 at the end of the three preceding weeks; one new case was admitted during the week. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2406, against 2585, 2512, and 2449 on the three preceding Saturdays; 216 new cases were admitted during the week, against 224, 219, and 204 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 282 and 271 in the two preceding weeks, rose again to 274 last week, but were 121 below the corrected average. The causes of 47, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Leicester, Bradford, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Burnley, Blackburn, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·1 and 24·6 per 1000 in the two preceding weeks, declined again to 22·3 during the week ending April 17th, but exceeded by 4·4 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns

Hosted by Google

ranged from 18·0 in Leith and 18·4 in Aberdeen to 25·6 in Perth and 26·0 in Edinburgh. The 665 deaths in these towns included 39 which were referred to measles, 39 to whooping-cough, 12 to diarrhœa, 7 to "fever" (principally enteric), 6 to diphtheria, and 4 to scarlet fever. In all, 107 deaths resulted from these principal zymotic diseases, against 104 and 95 in the two preceding weeks. These 107 deaths were equal to an annual rate of 3·6 per 1000, which was 2·0 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 29 and 33 in the two preceding weeks, further rose to 39 last week, of which 19 occurred in Glasgow and 19 in Edinburgh. The 39 deaths from whooping-cough exceeded by one the number in the preceding week, and included 22 in Glasgow, 5 in Leith, and 5 in Edinburgh. The deaths referred to "fever," which had been 6 and 3 in the two preceding weeks, rose again to 7 last week, of which 4 occurred in Glasgow. The fatal cases of diphtheria, which had been 9 and 4 in the two preceding weeks, rose again to 6 last week, and included 4 in Edinburgh, where two of the 4 deaths from scarlet fever were also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 146 and 153 in the two preceding weeks, were 154 last week, and exceeded by 44 the number in the corresponding period of last year. The causes of 46, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 38·5 and 35·9 per 1000 in the two preceding weeks, further declined to 28·2 during the week ending April 17th. During the thirteen weeks of last quarter the death-rate in the city averaged 40·2 per 1000, the rate during the same period being 18·4 in London and 22·4 in Edinburgh. The 189 deaths registered in Dublin during the week under notice showed a decline of 52 from the number in the preceding week, and included 36 which were referred to the principal zymotic diseases, against 47 and 41 in the two preceding weeks; of these, 15 resulted from measles, 14 from whooping-cough, 2 from scarlet fever, 2 from diphtheria, 2 from "fever," and 1 from diarrhœa. These 36 deaths were equal to an annual rate of 5·4 per 1000, the zymotic death-rate during the same period being 1·4 in London and 5·7 in Edinburgh. The fatal cases of measles, which had declined in the four preceding weeks from 46 to 25, further fell to 15 last week. The deaths referred to whooping-cough, which had been 9 in each of the two preceding weeks, rose again to 14 last week. The 2 fatal cases of scarlet fever showed a slight further decline from recent weekly numbers, and the 2 deaths from diphtheria corresponded with the number recorded in the preceding week. The 189 deaths in Dublin last week included 34 of infants under one year of age and 38 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a further decline from the high numbers recorded in recent weeks. Four inquest cases and 4 deaths from violence were registered; and 53, or more than a fourth, of the deaths occurred in public institutions. The causes of 10, or more than 5 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING MARCH, 1897.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during March in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 7·8 per 1000 of the population, estimated at 4,463,169 persons in the middle of this year. In the three preceding months the rates had been 10·7, 9·0, and 8·7 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Paddington, St. George Hanover-square, Marylebone, Hampstead, St. Martin-in-the-Fields, and Clerkenwell; while they showed the largest excess in Chelsea, Holborn, Bethnal Green, Mile End Old Town, Poplar, Battersea, and Wandsworth. Eight cases of small-pox were notified in London during March, against 3, 8, and 48 in the three preceding months; of these, 2 belonged to Strand, 2 to Poplar, 2 to Woolwich, 1 to Hackney, and 1 to Camberwell sanitary areas. There were 17 cases of small-pox under treatment in the Metropolitan Asylum Hospitals at the end of March, against 3, 8, and 43 at the end of the three preceding months; 8 new cases were admitted during the month, against 7 and 53 in the two preceding months. The prevalence of scarlet fever showed a further decline from that recorded in recent months; this disease was proportionally most prevalent in Chelsea, Bethnal Green, Mile End Old Town, Poplar, St. Saviour Southwark, Battersea, Wandsworth, and Plumstead sanitary areas. The Metropolitan Asylum Hospitals contained 2468 scarlet fever patients at the end of March, against 3601, 3246, and 2775 at the end of the three preceding months; the weekly admissions averaged 208, against 355, 245, and 228, in the three preceding months. The prevalence of diphtheria in London differed but slightly from that recorded in the two preceding months; among the various sanitary areas this disease showed the highest proportional prevalence in Chelsea, St. James Westminster, Holborn, Bethnal Green, Whitechapel, Mile End Old Town, Bermondsey, Wandsworth, and Camberwell. There were 776 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of March, against 829, 897, and 855 at the end of the three preceding months; the weekly admissions averaged 101, against 119, 105, and 101 in the three preceding months. The prevalence of enteric fever in London showed a further decline from that recorded in recent months; this disease was proportionally most prevalent in Kensington, Hackney, Bethnal Green, Whitechapel, Bermondsey, and Greenwich sanitary areas. Erysipelas showed the highest proportional fatality in Holborn, Bethnal Green, Limehouse, and Poplar sanitary areas. The twenty-three cases of puerperal fever notified during March included 3 in Fulham, 3 in Islington, 2 in Kensington, and 2 in Newington sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the five weeks ending Saturday, April 3rd, the deaths of 7441 persons belonging to London were registered, equal to an annual rate of 17·4 per 1000, against 17·6, 18·2, and 18·5 in the three preceding months. The lowest death-rates during March in the various sanitary areas were 11·7 in Hampstead, 12·8 in Paddington, 13·0 in Lee and in Plumstead, 13·1 in St. Martin-in-the-Fields, and 13·2 in Lewisham, (excluding Penge); the highest rates were 22·6 in Bethnal Green, 22·8 in Limehouse, 24·2 in St. Luke, 24·5 in City of London, 25·0 in Holborn, 27·6 in St. George-in-the-East, and 27·9 in Strand. During the five weeks of March 660 deaths were referred to the principal zymotic diseases in London; of these, 216 resulted from whooping-cough, 215 from diphtheria, 63 from measles, 63 from diarrhœa, 51 from scarlet fever, 45 from enteric fever, and 7 from small-pox. These 660 deaths were equal to an annual rate of 1·5 per 1000. The lowest death-rates from these diseases last month were recorded in Paddington, Westminster, Marylebone, St. Luke, Lee, and Plumstead; and the highest rates in St. Martin-in-the-Fields, Strand, Bethnal Green, St. George-in-the-East, Newington, and Bermondsey sanitary areas. Seven fatal cases of small-pox were registered in London during March, of which 3 belonged to Camberwell, 2 to Strand, 1 to St. Martin-in-the-Fields, and 1 to St. George Southwark sanitary areas. The 63 deaths referred to measles were less than a fourth of the corrected average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Bethnal Green, St. George-in-the-East, and Limehouse sanitary areas. The 51 fatal cases of scarlet fever were 30 below the corrected average number; the mortality from this disease showed no marked excess in any of the sanitary areas. The 215 deaths from diphtheria were 52 above the corrected average number; this disease was proportionally most fatal in Hackney, Shoreditch, Bethnal Green, Mile End Old Town, Bermondsey, Wandsworth, and Camberwell sanitary areas. The 216 fatal cases of whooping-cough were 125 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Fulham, St. Giles, City of London, Newington, Bermondsey, Lambeth, and Camberwell. The 45 deaths referred to enteric fever slightly exceeded the corrected average number; the mortality from this disease showed no

marked excess in any of the sanitary areas. The 63 fatal cases of diarrhœa were within 4 of the corrected average number. In conclusion, it may be stated that the mortality in London during March from these principal zymotic diseases was more than 33 per cent. below the average.

Infant mortality in London, measured by the proportion of deaths under one year of age to births registered, was equal to 130 per 1000 during March, and was below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in Hammersmith, Westminster, Hampstead, and St. Olave Southwark; and the highest rates in St. Giles, Strand, Holborn, St. Saviour Southwark, and Rotherhithe.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-LIEUTENANT-COLONEL I. B. EMERSON assumes temporary Medical Charge of the troops at Ipswich during the absence on leave of Deputy Surgeon-General W. A. Gardiner. Surgeon-Major S. F. Lougheed will shortly join at Woolwich. Surgeon-Captain M. J. Whitty proceeds to Hong-Kong. Surgeon-Colonel W. Graves has been appointed Principal Medical Officer of the Belfast District.

INDIA AND THE INDIAN MEDICAL SERVICES.

The following retirements are announced:—Brigade-Surgeon-Lieutenant-Colonel Hugh Johnstone (Bengal), Civil Surgeon and Port Health Officer, Rangoon, and Surgeon-Lieutenant Alfred Moore (Madras), both subject to Her Majesty's approval.

NAVAL MEDICAL SERVICE.

The following appointments are announced: — Fleet Surgeon J. C. B. Maclean to the Royal Marine Depôt, Walmer. Staff Surgeons: J. D. Henwood to the *Revenge;* Thomas E. H. Williams to the *Empress of India;* and M. O'Connell M'Swiny, lent to the *Hibernia*. Surgeon Sidney T. Reid, lent to the *Barfleur*.

CHARCOAL DRESSING IN MILITARY SURGERY.

In a small pamphlet issued by the Publishers' Printing Company, New York, Dr. S. Sherwell of Brooklyn claims to be the introducer of charcoal as a dressing for open wounds in field surgery. According to Dr. Matignon of the French army this method was originally devised in 1891 by a Japanese military surgeon named Kikuzi, but ten years previously, at the International Medical Congress in London, Dr. Sherwell read a paper advocating "the instant envelopment of wounds ..... in a sack or bag of charcoal, finely pulverised." It does not appear, however, that Dr. Sherwell ever reduced his theory to practice, whereas the results obtained by Kikuzi at Port Arthur and elsewhere, not only in gunshot and other wounds, but also in frost-bites, are said to have been strikingly satisfactory. The American claimant is of opinion that rice-straw charcoal cannot differ greatly from other charcoals, but in an editorial note to an article in a French medical journal,[1] to which he refers, some experiments are mentioned which would seem to prove that the former possesses peculiarly distinctive qualities, not only as regards softness and elasticity, but also in chemical composition. As the writer of the note in question observes in conclusion, "It is to be desired that further experiments should be undertaken, with a view to the differentiation of the various straw charcoals."

LEAN'S ROYAL NAVY LIST.

The latest issue of this indispensable publication is to hand and will be cordially welcomed by all who have anything whatever to do with our first line of defence. The information which has been brought up to date includes among other matters the war and meritorious services &c. of the officers of the Royal Navy and the Royal Marines; the dates of all commissions; dates of birth (flag officers, captains, and officers of Royal Marines), together with medals, clasps, honours, decorations, and rewards; famous battles against the names of the ships; the details from official sources of the gallant deeds for which the Victoria Cross, Albert Medal, and medals of the Royal Humane Society, Lloyd's Shipwrecked Mariners' Society, Liverpool Shipwreck and Humane Society, and Royal National Life Boat Institution have been awarded; appointments held by retired officers; causes of special promotions; fellows of the learned societies, and deputy lieutenants.

"Audi alteram partem."

THE QUESTION OF THE SECOND OVARY IN OVARIOTOMY.

To the Editors of THE LANCET.

SIRS,—The operation of ovariotomy, requiring little anatomical knowledge, I have always inclined to rank as one for which little surgical training was requisite. Its former reputation depended entirely on the terrible mortality that in years gone by attended the earlier operations, so that a certain amount of courage was necessary in order to undertake it. Great credit was therefore due to those who, by greater attention to aseptic methods and detail, brought the operation to the present degree of safety. Whilst from a surgical point of view a little coolness and courage with a very limited knowledge of the human body are all that are requisite for an ordinary case, it is nevertheless an operation which requires a large amount of common sense in dealing with adhesions and with complications that may be met with.

The question which will interest a great many at the present time will be the rule of the profession in dealing with the second ovary if in an early condition of disease; and without wishing to press strongly my views (which others may regard erroneous) I will state what with me have been the determining factors in practice. In the case of malignant disease no one would, I presume, hesitate to remove every particle of growth it was possible to clear away, so that opinions could scarcely differ if, on removing one ovary which was malignant, a nodule of growth was discovered on the other. Both should be removed. With simple cystic disease, where one ovary is extensively diseased and the other only in an early stage of cystic degeneration it would appear to me that the patient's age and condition of life must be the determining factors. It would, I believe, be generally conceded that with one ovary remaining, and that in a state of partial cystic degeneration, not only would menstruation be continued, but the possibility of impregnation and child-bearing (at any rate, for a time), for corpora lutea are to be found in the undegenerate portion. If both ovaries are removed, however healthy a prospect of life may be thus secured, the woman from that time forth is an unnatural monster, cut off from the next generation, and, if married with this condition secreted, would, I presume, be liable to be divorced. It has twice happened to me recently to be face to face with this position and I acted differently in the two cases. One was a patient under the care of Mr. George Flower of Yeovil. She was in her fortieth year and had had no child for many years. After removing a very large ovarian tumour from one side I found the other in an earlier stage of cystic degeneration. I removed both, telling her afterwards that she could not again become pregnant and that she would be relieved of the inconvenience of menstruation. The other case was a patient under the care of Mr. Challoner Clay of Fovant, Salisbury. She was only twenty-five years of age and was found to have a large unilocular cyst of her right ovary, which contained ten pints of fluid, and connected with the left ovary was a cyst as large as an orange. The right ovary was easily removed and the other was left. The view I took in this case was that at her time of life I had no right to cut her off from the chance of matrimony and of child-bearing. The remaining ovary was not likely to endanger her life for a considerable period, and in the meantime it might be possible for her to become a mother. Should the cystic degeneration increase rapidly there would probably be no great danger in operating a second time for the removal of the remaining ovary.

I am, Sirs, yours faithfully,

R. CLEMENT LUCAS, B.S. Lond., F.R.C.S. Eng.,
Surgeon to Guy's Hospital.

Wimpole-street, W.

"RIGHT-HANDEDNESS."

To the Editors of THE LANCET.

SIRS,—Professor Struthers' letter in THE LANCET of April 17th affords an excellent illustration of a fact to which I lately drew your attention[1]—namely, that in medical

[1] THE LANCET, April 3rd, 1897.

Hosted by Google

literature one constantly meets statements implying a belief that acquired characters are transmissible. Professor Struthers says: "On the hypothesis of unity of origin" (of the races of mankind) "the explanation of right-handedness is easy. One hand would naturally be fixed on; the young would be trained to use the same hand; and the influence of that on the left hemisphere of the brain would ere long give a hereditary or 'instinctive' tendency to prefer the right hand." It appears to me that this "easy" explanation involves an impossible assumption, and one which at the present day is very generally disputed by biologists. Will Professor Struthers explain how modifications *acquired* by the left hemisphere of the brain of the parent can so affect the germ cell—in which there are neither nervous nor muscular tissues—that, after long separation from the parent organism, it (the germ cell) will proliferate into an individual who is right-handed—i.e., who has inborn the peculiarity the parent acquired? Surely that part of Professor Struthers' explanation in which he says, "One hand would naturally be fixed on; the young would be trained to use the same hand," is all-sufficient, and there need be no appeal to what is practically a miracle. No one excepting those who have given special attention to the subject have any conception of how very much of the physical and mental parts of every man is individually *acquired*, and is therefore not inherited or transmissible in the biological sense, and none but those who have so studied the subject have any conception of how vast is its importance, not only to the student of disease and the biologist, but also to the sociologist, the philanthropist, the statesman, &c. For example, every man individually *acquires* the faculty of language and of bi-pedal progression in an erect posture; neither of these is instinctive or inborn, and therefore transmissible; and both result from the fact that the one generation acquires them by imitation from the preceding generation. It is probable, therefore, that most men are now right-handed merely because they acquire or learn this peculiarity from their elders, not because they are born with it. Professor Struthers himself says: "The preferential use of the right hand does not, according to my observation, show itself in very young children, but only after they have assumed the erect posture and begun active exertion."

I am, Sirs, faithfully yours,

Southsea, April 19th, 1897. G. ARCHIDALL REID.

To the Editors of THE LANCET.

SIRS,—Professor Struthers and I seem to afford each other mutual support. While I seek to show that (owing to the centre of gravity of the thorax being nearer the left fore limb than the right) our remote fore-footed ancestor and the crawling child would tend to use the right hand in preference to the left, Professor Struthers maintains that the visceral preponderance over the right leg of the *erect* man would tend to produce the same result. It appears, therefore, that both before and after attaining the erect position visceral preponderance makes for right-handedness. With regard to the feet, I would point out that the drill-sergeant and dancing-master traditionally insist on commencing to march or dance with the *left* foot, the reason being that the stability of the body, owing to visceral preponderance, is less disturbed by taking the left foot off the ground than the right. Left-handedness seldom shows itself so long as movement is mainly coarse and bilateral, but is noticed as soon as a child begins to use a spoon or a pen. Small degrees of hemiplegia are far from uncommon in young children (owing to slight damage to the cerebral cortex during birth), but the trifling disability of one hand is seldom noticed by the friends until the child begins to use the hands independently. I have seen many such cases. In all cases of so-called "writer's cramp" I am accustomed to inquire for "left-handedness" and to look for evidence of congential or infantile cortical lesions, and I have notes of several cases in which the evidence of such lesions, though slight, was complete. I have records of two cases of extreme left-handedness, in which the left arm was broken in childhood and was consequently carried in a splint for some weeks. This, however, did not in either case cure the left-handedness. I have notes of another case in which the right half of the body—face, limbs, and trunk—was obviously smaller than the left half, but the patient was not in the least left-handed. That there must be an anatomical cause for our almost universal right-handedness is certain, but the exceptional left-handedness may obviously be due to a variety of causes. One may be allowed to speculate as to whether people are ever ambi-dextrous (i.e., whether a left hand is ever equal to a really first-rate right hand). That the preferential use of the left hand is often due to a congenital cortical lesion I have no doubt and it may be that such persons have two second-rate hands instead of one first-rate hand.

I am, Sirs, yours truly,

Wimpole-street, April 20th, 1897. G. V. POORE.

THE PERIPHERAL ORIGIN OF SOME SPINAL CORD AFFECTIONS.

To the Editors of THE LANCET.

SIRS,—The question of the possible peripheral origin of some spinal cord affections is raised by the interesting communications from Dr. Semple and Dr. Taylor in THE LANCET of April 17th, "On Certain Symptoms of Spinal Cord Affections in Bicycle Riders." May I be permitted to call attention to a paper of mine entitled, "On the Etiology of Some of the System Diseases of the Spinal Cord,"[1] in which I put forward the view based partly on probability and partly on grounds of observation of the possible peripheral origin of some of these diseases? Dr. Semple and Dr. Taylor say of their cases that "it is not unlikely that in all of them there was produced, presumably through pressure, some condition of the nervous structures possibly analogous to that which obtains in pressure palsy," and "that it is possible that in the case in which the spinal cord became much involved the condition became an actual neuritis, and that the inflammation spread so as to set up a similar process in the spinal cord." In my paper to which I allude I endeavoured to show the likelihood of many cases of so-called lateral sclerosis, as also of posterior sclerosis (or "tabes"), being due to over-use of the motor and sensory apparatus, and suggested that affection of the peripheral nerves might spread to the cord. There are many corrections, additions, and omissions that I should like to make with respect to my crude paper on this matter, written so long ago, but my experience of late years goes to corroborate the view that a large number of cases of both pure and mixed examples of "spastic paralysis" and "tabes" are with the greatest clinical probability etiologically referable to over-use or irritation of peripheral nerves terminating in either skin or muscle.—I am, Sirs, yours faithfully,

London, April 19th, 1897. H. B. DONKIN.

"LACTOSURIA."

To the Editors of THE LANCET.

SIRS,—I have read with interest the article on this subject in THE LANCET of April 17th. Although the occurrence of sugar in the urine during lactation was described by various writers as being frequent, yet on investigating the literature on this subject I was unable to find that any prolonged and careful inquiry had been made. In conjunction with Dr. W. A. Turner I investigated a series of 100 cases[2] in order to answer the initial question, Is sugar always present in the urine of nursing women at some period of lactation? This question we were enabled to answer in the affirmative. In addition to the examination of the urine a daily note was made concerning the condition of the mammary glands, the quantity and quality of the milk, and the sucking and general nutrition of the child. As a result of our observations we concluded: 1. That sugar is present in the urine of women during lactation. 2. That sugar is present at some period in every case. 3. That in the majority of cases the largest amount occurs on the fourth and fifth days of the puerperium. 4. That the quantity depends on (*a*) the condition of the breasts; (*b*) the quantity and quality of the milk; and (*c*) the sucking of the child. Out of 100 cases the average quantity found was 0 35 per cent.—i.e., 1½ grains per ounce. 5. That when lactation is diminished or suppressed the amount of sugar diminishes or disappears. 6. That when the production and exhaustion of the milk are equal the amount of sugar is very small.

The suggestion that the quantity of sugar present in the

[1] Published in the volume of Brain for 1883.

[2] Transactions of the Obstetrical Society of London, vol. xxxiv., 1892, p. 473.

Hosted by Google

urine is an indication of value in choosing a wet nurse was made by Blot[3] in 1856. With this suggestion we could not agree, for in cases where large quantities of lactose were present in the urine the nutritive value of the milk, as gauged by the nutrition of the child, was inferior. The milk may be rich in lactose, yet poor in nutritive value, or for some reason more lactose is absorbed and excreted. It is important to remember that the larger amounts of lactose are found at the onset of lactation or at its cessation, especially where weaning has been recommended, as a certain amount of breast distension usually occurs.

I am, Sirs, yours faithfully.

Curzon-street, Mayfair, W., April 19th, 1897. F. J. MCCANN.

"SHOULD EPILEPTICS MARRY?"

To the Editors of THE LANCET.

SIRS,—Sexual reproduction with its natural variations is as inadequate as Dr. Campbell's previous explanation of coincidence to account for the cases I recorded, nor can I accept the "dictum of an eminent biologist" when it is opposed to a plain matter of fact. Dr. Campbell's doubt of the transmission of gout is contrary to all experience, his explanation of inherited baldness savours too strongly of the *virtus dormitiva* to be intelligible, his argument of circumcision and the docking of horses needs to be viewed in the light of the functional insignificance of the parts docked, and the proneness of the transplanted negro to tubercle has been otherwise explained, but it does not bear on this question.

Dr. Reid dismisses the theory of pangenesis, adopts the view of Weismann, and says "the germ cell, so far as we know, is indebted to the other cells only for shelter and nutrition. This consideration renders unbelievable the hypothesis that acquired traits are transmissible." Even allowing him so to beg the question of the limited dependence of the germ cell, "so far as we know"—and we know nothing whatever about it—this consideration does nothing of the sort. If the germ cells depend for shelter and nutrition on the other cells they are therefore as liable to modification by them as any organism is to the influence of its surroundings. The crabs and other animals that made their home in such caves as those of Kentucky depended for shelter and nutrition on their surroundings no more and no less than the blastogenic cells depend on their surrounding cells. Through disuse of their eyes for successive generations they finally lost those organs, and we find the crab in which "the footstalk of the eye remains, though the eye is gone." Now, does any sane person contend that such a result is a coincidence, or is it a natural variation of sexual reproduction, or is it a proof of the continuity of the germ plasm? It is, of course, an example of the same process of heredity, though slower in operation, that is at work in those cases of the transmission of the results of lesions that I have recorded.

The attitude of those who follow Weismann's theory is well illustrated by your extract from Dr. Pearse's communication; they have accepted a hypothesis, and if the facts will not tally with it, then so much the worse for the facts. There is no mere hypothesis under the sun that is sufficient to justify us in concluding *a priori* that acquired lesions *cannot* be transmitted. Surely the more scientific method would be to investigate cases of transmission, and then to frame a hypothesis that will tally with established facts.

I am, Sirs, yours faithfully,

St. John's Wood-park, N.W., April 3rd, 1897. W. G. THISTLE.

*** This correspondence must now cease.—ED. L.

"THE MIDWIVES REGISTRATION BILL."

To the Editors of THE LANCET.

SIRS,—The hopeless muddle into which the promoters of midwife registration have fallen must be my apology for again trespassing on your space in order to supplement my note appearing in THE LANCET of March 27th. The time for academic discussion and for destructive criticism and personal recrimination is past, and the public, Parliament, and the medical profession, or that part of it, at least, who take any interest in the subject, anxiously look for a solution. This is not to be found in the Bill now before the Commons: (1) because it will register the *bonâ-fide* midwife of two years' standing—i.e., the "Gamp" and other untrained and ignorant women who practise midwifery and, according to the medical advocates of registration, scatter disease and death broadcast; this alone would condemn the Bill; (2) the Bill makes no provision for after-nursing, which is a fatal defect if its promoters intend it to apply to "the poor"; (3) there is no provision for medical or surgical aid in emergencies or for the payment of medical men or midwife in such cases occurring among "the poor"; (4) its administration is utterly at fault, as a central board largely composed of specialists know absolutely nothing of local wants and circumstances; and it is manifestly unfair and impolitic to thrust police duties on the medical officer of health or other medical man, whose office, under the Bill, as detective, spy, and informer would be invidious and degrading. Thus, while the Bill would intensify all the existing evils it would (5) sow discord among male and female midwifery practitioners, promote slander and backbiting, and to a large extent deprive the poor of the prompt assistance and sympathy of medical men, whether they are paid or not, and which is denied them by the qualified midwife unless her fee is paid in advance. It is absurd to say, as the promoters express it (*vide* the *Times*, Feb. 26th), "that the midwife must always stand entirely outside the medical profession." On the contrary, when registered she will be an integral part of it, and severely compete with fully qualified medical men, while she is dependent upon them in cases of difficulty and emergency. This must strike the most obtuse as grossly unfair. The promoters of registration give away their case in the following sentence (*vide loc. cit.*): "The utmost that is proposed or could be done is to regulate the practice of those who take the name of midwife; nothing will or can prevent *any person* whatever from practising in this capacity. We demand that the *name* of midwife shall be protected, and shall be *in itself* a guarantee that the bearer of it is competent for the work she undertakes!" In the *name* of common sense, what does the poor woman whose slender means are not equal to a fee of more than 5*s*. or 7*s*. 6*d*. at the outside care for a diplomated and registered midwife, clad in gown and ribbons, who requires another woman to wait upon her and to do the housekeeping, washing, and cooking? And if "any person" can practise midwifery under the registration Bill, how will this meet the case of its medical supporters, who look to it to abolish puerperal fever and the grievous maladies due to the practice of midwifery by the incompetent? The scheme of the Bill, as I said in my former letter, stands "self-condemned," and we must seek for a better.

Having had the midwife question under my observation for nearly five years in the parish of East Sheen, and having regard to the abuses which gradually crept in under the ægis of catering for "the poor," who were at first required to pay only 5*s*, then 7*s*. 6*d*., and with an increase of the wage limit from 30*s*. to 50*s*. per week an enhanced fee of 10*s*., and finding the comparatively rich taking advantage of the midwife's fees and "the poor" left very much to their own resources, I took action in order (1) to have the wage limit reduced again, and in this I succeeded; and (2) to put forward "a scheme" which was intended to meet the requirements of the working and small shop-keeping classes and at the same time to make an honest effort to solve the midwife question to the advantage of the public, the profession, and the midwives themselves. This was done publicly at the annual meeting of the Local Nursing Association (who employ a professional nurse and a diplomated midwife) on Feb. 4th. The vicar was chairman and about forty representatives of the *élite* of the parish were present, and after full discussion and subsequent examination of my proposals in committee they wrote: "The committee authorise me to say that they consider the changes quite impracticable; the class of women whom it is desired to help could not possibly pay for both doctor and nurse. The result would be that they would employ neither, and would revert to the unskilled though kindly meant help of their neighbours. This is exactly what the society desires to avoid." It is none the less what I desire to avoid, as will immediately appear. But the promoters of registration should carefully note the terms employed and the contention of the local society, as these are distinctly adverse to the principle of the Bill, which registers the "Gamp" and recognises the "friendly neighbour." The local committee, however, recognised the injustice of a 50*s*. wage limit, which in two years had reduced the midwifery practice of the medical men from 50 to 60 per cent., and the

[3] Comptes Rendus, xliii., p. 676, 1856.

Hosted by Google

limit is now 30*s*. My proposals were made for a parish of 7000 odd, and for an average birth-rate of 180, and if sound should be generally applicable. These are divided for comparative purposes into three sixties: First sixty (wages from 30*s*. to 40*s*.) to contribute 15*s*.; second sixty (wages from 20*s*. to 30*s*.) to contribute 10*s*; and third sixty (wages 20*s*. and under) to contribute 5*s*. (1) The patients to find their own nurses, or contribute towards a trained nurse's salary; (2) the "destitute" to be attended under Poor-law as at present; (3) an honorarium of 5*s*. to be added to each of the above contributions, making medical men's fees 20*s*., 15*s*., and 10*s*. respectively, or an average of 15*s*. each; (4) all resident medical men who practise midwifery to be on the staff and the women to choose their own medical man, and the medical men to be *ex-officio* members of the managing committee with monthly or quarterly meetings; (5) the present midwife to be retained as *obstetric nurse* at a reduced salary or another appointed; and (6) the obstetric nurse to act in *all* cases under medical supervision and do all that is usually done by a *monthly* nurse (except sleeping in the patient's house) should the patient desire her services.

In dealing with the cash account on the basis of the income of the local nursing association—viz., £270—I secure a balance of £135 for distribution among the medical men, after allowing a salary of £60 each to a trained sick and obstetric nurse and £15 for incidentals. Of the £270 income, £90 would be contributed by the women under the above scale, leaving £180 to be raised by subscription, donations, &c. Some rich parishes would no doubt pay their nurses more. Mortlake pays £100 per year to its sick nurse, and it is money well spent; she is a Jubilee nurse with three years' training, and is a boon to "the poor" of the parish. The Jubilee Institute send out trained obstetric nurses at salaries of from £25 to £30, but costume, laundry, and maintenance must be found for them. Every parish, however, has one or two suitable women for obstetric nursing purposes, and local training centres could be fixed for them, and their salaries would be very much less, as they would generally have a cottage of their own in country places. The Mortlake midwife is paid £80 per annum, but began at £60.

Now, if we had a Bill creating obstetric nurses on lines parallel to sick nurses in every parish in the land, and if, like many other Bills, its adoption were optional, there could be no better machinery for its administration than voluntary associations after the type of the Mortlake Association, modified as herein proposed and adapted to local circumstances. This proposed Sick and Obstetric Nurses Bill would assail no interest and would be welcomed by all, and it would open out an immense field of honourable employment for active and intelligent women with a vocation for nursing. I have already pointed out the unfairness of the proposal to create and register a class of quasi-independent midwives to compete with private practitioners of both sexes, and if there is a loss of £135 at an average of 15*s*. per case on 180 cases, it is not so difficult to calculate the loss on the annual birth-rate of the country, apart from the loss of life and health and domestic happiness.

Any Bill which fails to deal with the great mass of the "parturient poor" (and the present Bill fails woefully in this respect) will be unsatisfactory, and no Bill would be complete without a clause empowering boards of guardians, and if need be enforcing them, to contribute towards the maintenance of trained "obstetric nurses" for the poorest of the population. Sick nursing is already provided for by the Consolidated Orders, and has been taken advantage of by the Richmond board to contribute £10 per annum to the funds of the local association. The spirit of the times is against extending medical relief to any but the really "destitute," and out of a population of over 7000 I have only attended twenty such midwifery cases in four years. As things are, and as they would be under the proposed registration scheme, "the poor" would find themselves just where they are, while the trained midwife would find her practice among the patients of private practitioners. And in granting "orders" for confinement on district medical officers much less stringency should be observed by relieving officers, whose hands are tied by the legal phrase "destitute," which in practice means "wholly unemployed" or only "casually employed." Men earning £1 a week, or even more than this, and who have to support a wife and several children, can neither pay medical man nor midwife and are perforce at the tender mercy of the "Gamp" and "friendly neighbour."

I sincerely hope we are on the eve of a solution of this vexed question, and if Parliament cannot find time it may still be solved to the satisfaction of all parties on the lines indicated herein.—I am, Sirs, yours faithfully,

ALEXANDER MCCOOK WEIR.

East Sheen, March 29th, 1897.

HOSPITAL REFORM.

To the Editors of THE LANCET.

SIRS,—At a meeting of the Plymouth Medical Society on Wednesday, April 14th, the following resolutions were carried:—

1. That this meeting, although not pledging itself to the particular recommendations of the Hospital Reform Association, approves of its principles.
2. That a recommendation be sent to the committees of the various hospitals, dispensaries, &c., of the three towns asking them to appoint an investigation committee, whose duty it shall be to inquire into the circumstances of the persons applying for relief, and, if they find it necessary, to appoint an inquiry officer, and so limit the assistance given to the necessitous poor only.

I am, Sirs, yours truly,

W. L. WOOLLCOMBE, Hon. Sec.

The Crescent, Plymouth, April 19th, 1897.

"RECORDS OF FATALITIES UNDER ANÆSTHETICS."

To the Editors of THE LANCET.

SIRS,—Under this heading in THE LANCET of April 3rd you refer to a case which occurred in the Parish Infirmary, Liverpool, and as I happened to be the anæsthetist on that occasion I take this opportunity of informing you that there was *no* anæsthetic of any kind administered *after the patient first showed signs of collapse*. Trusting you will excuse delay,

I am, Sirs, yours faithfully,

THOMAS HENRY MOYLES,
Resident Medical Officer.

Parish Infirmary, Liverpool, April 13th, 1897.

THE NEW KOCH TUBERCULIN.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow us to inform your readers through your columns that we are now in a position to supply the new Koch Tuberculin, having received a consignment from the works? Thanking you in anticipation,

I am yours truly

(Pro Farbwerke vorm. Meister, Lucius, and Brüning),

St. Mary-axe, E.C., April 15th, 1897. F. DIXON.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Queen's Diamond Jubilee.

THE Lord Mayor's committee for the permanent commemoration of the Queen's Diamond Jubilee have decided by a majority which was by no means overwhelming to commemorate that auspicious event by the erection within the city of a central nursing institution for nursing the sick poor in their own homes, with a view to it becoming a training centre in the North of England. Another proposition, which obtained the support and sympathy of the working-class representatives on the committee, advocated the erection of a central People's Hall in the city, where the working classes could meet in social intercourse and also transact the business of their societies, tontines, &c.; in fact, to serve as a huge club for their benefit. Mr. W. P. Hartley advocated the adoption of both schemes, and with his customary liberality and large heartedness offered to contribute £500 towards each of these worthy objects. Mr. William Rathbone strongly urged the claims of a nursing institution, and submitted that one hall would be of little use, but that several would be needed to meet the requirements of the working classes from all parts of the city, a provision which he believed before long would be made conjointly by private beneficence and the City Council. On the other hand, there were many reasons for making Liverpool a centre for extending and completing the system of nursing the poor in their own

Hosted by Google

homes. In the first place it was essentially a Liverpool scheme, the district nursing system having originated in Liverpool. Within five years of its establishment the whole city was divided into districts in charge of ladies and nurses. As it now existed, even in Liverpool, the system was imperfect. Moreover, this was the method of commemoration which the Queen herself preferred. He felt sure that a central hall would not be one-tenth part of the benefit to the working classes. A proposition to adopt both schemes was rejected by a majority of five. The number of district nurses now engaged in nursing the sick poor of Liverpool in their own homes amounts to twenty-two.

Sanitary Science Classes at University College, Liverpool.

The arrangements for the lectures and demonstrations on Sanitary Science to be delivered at Ashton Hall, University College, in conjunction with the technical classes under the city council at the Liverpool School of Science, are now complete. They have been especially designed for persons desirous of qualifying as sanitary inspectors, but are also open to all interested in sanitary science, such as teachers, lecturers, builders, foremen of works, surveyors, architects, and others. The laboratories in University College are thoroughly equipped for the more advanced study of hygiene, bacteriology, and diseases of animals, and are under the supervision of the Professors of Pathology and Hygiene. A museum has been formed in connexion with them which contains an increasing collection of diseased animal tissues and of models illustrative of the various sanitary appliances and methods; in fact, it will become the Parkes Museum of Liverpool. The corporation have given a grant of £90 towards the purchase of apparatus, and also a yearly grant for evening lectures. The classes will be under the management of a board consisting of representatives of the city council and University College. Candidates for the sanitary certificates of the Victoria University are required to devote at least two years to their course of training. At the end of the first year they are required to show a competent knowledge of elementary physics and elementary hygiene, and will also receive credit for a knowledge of elementary inorganic chemistry, of mensuration, and of free-hand drawing. The examination at the end of the second year will comprise sanitary law, sanitary engineering and appliances, objects and methods of inspection of nuisances, food inspection, and methods of disinfection. The Victoria University examination for certificates of sanitary knowledge will be held in July in each year. The fee for the ordinary examination and certificate is £2 2*s*.

Sanitary Inspectors' Association.

The tenth annual meeting of the North-Western and Midland Sanitary Inspectors' Association was held on the 10th inst. in the Royal Institution, Liverpool. The following appointments for the year were made:—President: Mr. Francis Vacher, medical officer of health, Cheshire County Council. Vice-presidents: Dr. E. W. Hope, medical officer of health, Liverpool; Mr. Edward Sergeant, medical officer of health, Lancashire County Council; Dr. William Carter, Liverpool; and Dr. George Reid, medical officer of health, Staffordshire. Chairman of Council: Mr. William Urquhart. Hon. Treasurer: Mr. N. Coates, Liverpool. Hon. Secretary: Mr. H. H. Spears, Waterloo.

April 20th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Glasgow University.

THE graduation ceremony formally closing the winter session took place on the 13th inst. The honorary degree of LL.D. was conferred upon six gentlemen, including Surgeon-Major-General James Jameson, M.D. Glasg., Director-General of the Army Medical Department, and Professor Ramsay, F.R.S., University College, London. Surgeon-Major-General Jameson is an alumnus of the University, where he took his medical degree in 1857; Professor Ramsay is also an alumnus of the University and was assistant to the Professor of Chemistry until 1880, when he was appointed to the Chair of Chemistry in University College, Bristol. Six gentlemen received the degree of M.D. To two of these "commendation" was awarded—viz., to William W. Don, M.B., for his thesis on "Thyroid Therapeutics" and to Walter King Hunter, B.Sc., M.B., for his thesis, "A Contribution to the Etiology of Beri-beri." The class medals in the Faculty of Medicine have been awarded as follows: Midwifery, Samuel S. Sloan; Materia Medica and Therapeutics, Alexander Laurie Watson, M.A.; Medicine, William K. Hutton, M.A.; Clinical Medicine, John Crow, Robert Nelson, and Alexander Wilson; Surgery, William Martin, M.A., B.Sc., and James A. Mitchell; Clinical Surgery, William Martin, M.A., B.Sc., James Rankin, B.Sc., James A. Mitchell, and James Davidson, M.A.; Physiology, James C. Rose and Andrew Mair; Anatomy, John M'Gilchrist and Alexander Munro; Zoology, David Kyle; Chemistry, Alexander V. Lothian, M.A.; Pathology, Robert Fullarton, M.A.; Physics, William M. Brown; Diseases of the Ear, George Clark and William Webster; Diseases of the Throat and Nose, James D. Cochran. Principal Caird presided at the ceremony and delivered an address dealing with the influence exercised by a university education. The summer session for the medical classes opened to-day. Professor Simpson has obtained leave of absence on account of ill-health, and it is with much regret I hear that Professor Coats is so unwell that he cannot be expected to conduct the class of practical pathology during the present session.

Glasgow Hospital Sunday.

The committee in their annual report announce that the total sum collected last year was £4342 17*s*. 4*d*., being an advance of £273 15*s*. 4*d*. on the preceding twelve months. In addition, the committee acknowledge the receipt of £5204 7*s*. 6*d*. from the trustees of the Guesdon bequest. Both sums have been divided among the three general hospitals.

Medical Appointments.

Mr. Peter M'Bryde, M.B., C.M. Glasg., has been appointed physician for diseases of women in the Glasgow Central Dispensary; Mr. C. O. Hawthorne, M.B., C.M. Glasg., has been appointed examiner in physiology to the Conjoint Board for Scotland (triple qualification); Mr. J. Grant Andrew, M.B., C.M. Glasg., and Mr. T. W. Jenkins, M.D. Glasg., have been elected assistant surgeons to the Victoria Infirmary, Glasgow; and Dr. Leitch has been unanimously elected chairman of the Gourock School Board. At the recent election of a School Board in Glasgow there were two medical candidates; one of these, Mr. Archibald Sloan, M.B. Glasg., was elected, but Mr. James Erskine, M.B. Glasg., was unsuccessful.

April 20th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Charge of the Lunatic Poor.

THE Board of Commissioners for the General Control of Asylums for the Lunatic Poor in Ireland has been re-established as follows: Mr. Justice Holmes, Mr. Thomas Robertson (chairman of the Commissioners of Public Works), Dr. O'Farrell (inspector of lunatic asylums), Sir Francis Cruise, M.D. Dub., Mr. Charles Kennedy, and Mr. J. Malcolm Ingles.

Coleraine Cottage Hospital.

At a large and representative meeting of the inhabitants of Coleraine, held on April 13th, it was decided, on the motion of the Right Hon. Sir H. Bruce, Bart., D.L., that considering the great benefit that Coleraine has already enjoyed by the establishment of the Cottage Hospital and District Nursing Institute, the best way of commemorating the Queen's Jubilee was by raising funds so as to place the hospital on an independent basis, and to further increase its efficiency in such manner as may be deemed advisable. At the conclusion of the meeting nearly £200 were subscribed.

The Queen's Jubilee Commemoration.

In addition to what is being done in Coleraine and in Belfast (where the fund to build the new Victoria Hospital amounts now to over £78,000) to commemorate the Queen's long reign the ladies of county Down, under the patronage of Lady Dunleath (whose husband gave £1000 to the new hospital in Belfast), have formed a committee for the purpose of raising a sum of £5000 for the improvement of the County Infirmary in Downpatrick. It is proposed to build a new operating-room and better quarters for the nurses, and to make other much needed improvements, as well as to form a

Hosted by Google

permanent addition to the endowment of the infirmary. The Duchess of Abercorn is also making a strong effort to raise money to build the new County Hospital for Tyrone in Omagh.

The Funeral of Professor Townsend of Cork.

The funeral of Professor Townsend was one of the most remarkable which has been seen in Cork for a long time. The hearse was preceded by nurses from the Louth Infirmary and a large body of medical students from Queen's College. After the hearse came the immediate relatives, and they were followed by practically all the medical men in the city walking in a body. The general public were largely represented, and the floral offerings were so numerous that it was necessary to have them conveyed to the grave in a special landau. Professor Townsend took a great interest and an active part in the organised resistance of the medical profession to the encroachments of the clubs, but his action gave rise to no bitter feelings against him amongst those whom he felt it his duty to oppose.

April 21st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Academy of Science.

M. LANNELONGUE opened a discussion upon injuries to the skin caused by the Roentgen rays, and related a case reported by M. Sorel, who had seen two abscesses produced in the chest-wall in an adult whose thorax had been "skiagraphed." M. Lannelongue regretted that no examination of the pus from these abscesses had been made. He added that at his own hospital he had seen severe burns of the skin in children who lived in a shady courtyard, the burns being due solely to the rays of the sun reflected from the sandy floor of the yard. In solar light there were, he said, trophic rays, which, like the x rays, produced profound chemical changes in the cell. Mr. William Crookes, F.R.S., was present at the meeting and asked the permission of the president to say that he had never seen any case of burns from x rays, although he had been working for a long time with skiagraphic apparatus. He considered that individual disposition must play a great part in their causation. M. Remy and M. Contremoulins, who have obtained interesting results by photographing organs, the vascular network of which had been injected with saline solution, so that the skiagraphs showed all the most delicate ramifications of the vessels, brought forward a method for the localisation of a foreign body in the tissues by means of the x rays.—Among other interesting communications made to the society was a plan for treating certain nervous diseases by an electrical current interrupted according to a regular musical rhythm. The interruptions are regulated, not by an ordinary scale, but by a musical box or some other mechanical musical instrument; the current thus brings about muscular contraction with the rhythm of the measure employed, whether a waltz, a jig, or a solemn prayer. As the effects of suggestion are also brought into play most interesting indications of muscular activity are obtained.—Another experimenter, M. Cornevin, has applied the method of microbial vaccinations to what he terms "anti-alkaloidal vaccination." He heats the alkaloid ricinine, the poisonous principle of castor-oil beans, for two hours at a temperature of 100° C. He finds that he can then inject pigs with this alkaloid without giving rise to any symptoms of poisoning, and also that they become immune to a dose of pure, unaltered ricinine. Colza seeds, upon which pigs are frequently fed in the country, sometimes contain castor-oil beans which have been mixed with them, and severe cases of swine poisoning have occurred. Animals, however, vaccinated by M. Cornevin's method escape.

The Provisioning of Ships' Boats in View of Wreck.

In the case of some shipwrecked sailors belonging to St. Nazaire, M. Langlois has made an interesting inquiry into the causes of death by starvation among those adrift in an open boat after a shipwreck. As a result he demands that provisions, prepared beforehand and packed in a watertight compartment, should be carried in all lifeboats. He considers that the quantity of these provisions should be calculated exactly so as to allow for 3000 calories per man per day and two litres of drinking water. In his opinion it is because the food taken is of the wrong kind that shipwrecked men die. Fats and condensed milk are most valuable; alcohol is harmful and useless except in very small doses for its moral effect in keeping up the spirits. M. Langlois' ration for twenty-five men for ten days would weigh half a ton for solids and as much again for water. In making his calculations he has taken into account the loss of heat which a man undergoes when wet either by rain or sea water. Finally, he recommends that there should be frequent lifeboat drills. At St. Nazaire it has sometimes taken six hours to get a life-boat into the water and the crew in their places; and, in addition, the crews, though not hurried, and in broad daylight with a perfectly calm sea, have smashed four boats in letting them down.

Letters of Identification for Lunatics.

An unfortunate accident has recently occurred to a family owing to neglect of prefectoral regulations. A merchant who had begun to show signs of cerebral fatigue from overwork asked that he might undergo hydropathic treatment in the departmental asylum. He came out perfectly well, and continued his business. Two months later, on returning home one day he found a letter addressed to his wife from the prefecture and the envelope of this letter had upon it in large letters, "In the matter of the lunatic X." The unfortunate man, seeing himself stigmatised as a lunatic upon an envelope which all his business house could have read, was seized with a sudden cerebral hæmorrhage and died almost instantaneously. There has been naturally much unfavourable criticism of a system which allows of the sending of letters endorsed in this fashion by employés. The letter, it should be added, was simply a demand for the payment of a small sum still owing for the man's treatment while in the hospital.

Premature Burial.

A conference, organised by the Société Française d'Hygiène, has just been held at the Sorbonne upon the best means of preventing premature burial. Count Karnice Karnicki gave a description of his apparatus, which has been much discussed in the press. At the slightest sigh on the part of the supposed corpse air and light enter the coffin, a bell rings loudly, and a flag indicates the place of the tomb in the cemetery. Several Parisian journalists have allowed themselves to be enclosed in coffins for the purpose of experiment, but the medical profession is less enthusiastic than the public as to the merits of the invention. Mere putrefactive swelling of the corpse would probably suffice to set the apparatus in action, for the starting point of all the signals is a little button which the chest of the body would graze at the slightest movement.

Private Hospitals.

The Municipal Council of Paris has held a long discussion with regard to private hospitals and the conditions under which they should be allowed to keep open. The Prefect of Police has recognised the fact that there exists at the present time no measure of surveillance for these institutions, and asks if inspection is not necessary from the hygienic point of view, quoting the precedent that there are inspectors of madhouses. Accordingly he proposes to submit to the Council of Hygiene every application made to him for the opening of a new establishment, although the Council of Hygiene has decided to refuse reply to applications of this kind, so as to be free from all responsibility on these matters. Many fantastic propositions have been put forward by the municipal councillors for the regulation of private hospitals, among others one forbidding any *clinique* to be opened unless it is founded by former *internes* of the Paris hospitals. The Prefect of Police requires that all deaths occurring in these institutions shall be at once reported to the police.

April 20th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Italian Students in Berlin.

THE visit of Italian students and graduates announced by your Rome correspondent in THE LANCET of April 17th took place just before Easter. On April 14th a party of about 300 members of nearly all the Italian universities, including students of the different faculties, arrived here and

Hosted by Google

were cordially received at the railway station by an assemblage, including professors and students of Berlin University and the Italian Ambassador. Both Italian and German students were in academic costume, the Italians wearing caps which showed the colours of their respective faculties. The two nationalities were introduced to one another by the Ambassador, and conversation is reported to have been at first rather difficult, but was eventually accomplished by means of a mixture of Latin and French. In the evening the guests were entertained at a "Commers," and were initiated into the science of consuming large quantities of beer, for which German students rightly enjoy a great renown. An address was delivered by the Rector, Professor Hinschius, who in perfect Italian proposed the health of King Umberto; Professor Massoni of Naples replied, and in his turn proposed the health of the German Emperor. A student, Signor Tonta of Pavia University, on behalf of the visitors presented a memorial plate, which will be placed in the *aula magna* of the university. The following days were spent in visits to the buildings occupied by the different faculties. The medical men were shown over several of our great public and private hospitals, among which mention may be made of the beautiful Friedrichshain Hospital, the university laboratories, and other places of interest. In the evening Italians and Germans were frequently seen fraternising together. The visitors will in the next place proceed to Leipzig and Munich.

The Proposed Reform of the Public Health Service.

The reform of the public health service, which has for a long time been greatly desired both by the medical profession and the public, has hitherto been postponed for financial reasons, but seems now to have become an accomplished fact. A report of a meeting of the Association of Medical Officers of Health appeared in THE LANCET,[1] and in this article I gave a short account of the present organisation, mentioning as the principal drawbacks of the service, firstly, the small salary, which naturally induces the medical officers to engage in private practice, and secondly, their subordination to the administrative authorities. The Government has now ordered the appointment of a Royal Commission to meet in Berlin, consisting of medical officers of health in actual employment, all the medical and some non-medical members of Parliament and commissioners nominated by the Government. The medical papers have published the Government proposals, which are to be considered first by the Commission and afterwards by Parliament; they are substantially as follows: The appointments of medical officer of health and medical expert to advise and give evidence in the law courts, which have hitherto been held conjointly by the medical officer of health (Kreisphysicus), will henceforth be separated. The medical officers of health will have to deal with hygienic questions exclusively, whilst the law courts will have to appoint special officials for medico-legal work. The office of surgeon of a circuit (Kreiswundarzt), who acted as an assistant to the Kreisphysicus, is to be abolished; also the provincial medical boards (Provincial-Medicinal-Collegium) are to be dissolved. The new medical organisation will be as follows: The medical department of the Ministry of Public Instruction will be the central authority, and will remain as at present. In each government district (Regierungsbezirk) a district medical officer (Regierungs-medicinalrath) will be appointed, who will advise the district government in matters of public health. His special duty will be the control of pharmacies, druggists, dispensers, private hospitals, and asylums, according to the existing laws, by-laws, and regulations. He will deal with all matters of ordinary occurrence, but in questions of exceptional importance he will be assisted by the district board of health (Bezirksgesundheitsrath). This board will consist of the president of the district as chairman, the district medical officer, together with one of his subordinate officers, the director of the provincial public health laboratory, and two members of the medical profession. The board will meet whenever convened by the chairman, and in any case not at longer intervals than once a year. Each district is divided into a number of circuits (Kreis). For each of these circuits a medical officer (Kreisarzt) is to be appointed, who will be subordinate to the district medical officer. In contradistinction to the present system the Kreisarzt will henceforth be a fully-salaried Government official and will enjoy all the rights and privileges of such; he will also be entitled to a pension when he retires. He must not engage in private practice, but will be eligible for the offices of hospital physician or surgeon, medical officer of a railway, poor-law medical officer acting under a municipality, &c. He will be required to advise the head of the circuit (Landrath) and will control the licensed midwives, nurses, pharmaceutical chemists, &c., of the circuit. He will, therefore, have to travel from time to time through his circuit and to enter into communication with the local medical practitioners. In urgent cases, especially in the time of an epidemic, he will be authorised to take measures independently of the local authorities, but he will be bound to inform them of his proceedings. He will also be assisted by a board of health (Kreisgesundheitsrath) presided over by the Landrath, and composed of from six to twelve members, medical and non-medical. The duties of this board are the same as those of the district board, but are, of course, confined to the circuit. In the larger towns municipal boards of health are also to be formed, and if the town has a garrison a medical delegate from the garrison has to take part in the proceedings. The office of member of a board of health will be an honorary one, but medical men, although by law exempt from several honorary obligations—such, for instance, as the liability to serve on juries—are not entitled to refuse an election to a board of health. One of the principal innovations of the new system is the institution of provincial public health laboratories. Each province is bound to provide at its own expense a laboratory, where all the microscopical examinations, chemical analyses, and other inquiries of a like kind will be conducted according to the order of the medical officer. Hitherto such work has been done either in private laboratories or in the university laboratories or sometimes in the Imperial Health Office. The latter will, of course, continue to be consulted in difficult cases, but will no longer undertake routine work. The proposals of the Government are undoubtedly a great improvement on the present system; they will, however, be certain to undergo some alteration, both at the instance of the Commission and also in Parliament.

Bacteria in Ink.

It sometimes happens that a trifling scratch or puncture made with a pen gives rise to dangerous septicæmia. The chemical constituents of the ink which is introduced by the pen into the wound are not capable of producing septicæmia, but microscopical examination proves that the ill effects are due to the liability of ink to contain pathogenic bacteria. Dr. Marpmann of Leipzig has recently published the results of the microscopical examination of sixty-seven samples of ink used in schools. Most of them were made with gall-nuts, and contained saprophytes, bacteria, and micrococci. Nigrosin ink, taken from a freshly-opened bottle, was found to contain both saprophytes and bacteria. Red and blue inks also yielded numerous bacteria. In two instances Dr. Marpmann succeeded in cultivating from nigrosin ink a bacillus which proved fatal to mice within four days. This ink had stood in an open bottle for three months, and the inference to be drawn from the inquiry is that ink used in schools should always be kept covered when not in use.

April 20th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Nature-study en Fête.

APRIL 14TH witnessed the twenty-fifth anniversary of the birth of the "Stazione Zoologica" at Naples, an institution which has an epoch-making record in science as the mother and the model of many other "Stazioni" of the kind, one of the latest of which is that established three years ago on the coast of Norway. The Bay of Naples, apart from its incomparable scenery, had long been known to biologists for its wealth in marine flora and fauna; and the history of its having come to be, by a sort of scientific annexation, the favourite dredging-ground of German nature-students has already been told in THE LANCET.[1] Italy, however, had to

[1] THE LANCET, Sept. 26th, 1896, p. 915.

[1] THE LANCET, May 12th, 1894; "In the Wake of the Congress."

Hosted by Google

be transformed into a united kingdom before that annexation could be made *un fait accompli*, and it was not until the spring of 1872 that the German Court and the German Government succeeded in founding the "Stazione Zoologica," which is now the resort of nature-students from all parts of the world. Its first director was the distinguished biologist who still remains its inspiring genius, Geheimrath Professor Anton Dohrn, M.D; and from the outset he was fortunate in his working staff, one of whom, Professor Ugo Eisig, is still at his post, and, indeed, took a prominent part in the recent commemoration. Even more fortunate was Professor Dohrn in his wife, who, with noble self-abnegation, sacrificed her whole marriage portion to promote the efficiency of the then infant "Stazione." How the institution has developed and expanded is now familiar history—the most significant feature about it being this: that its "Morphologisches und Physiologisches Laboratorium für Meeres-Zoologie und Botanik" is now frequented by students from both hemispheres, and that many European and Transatlantic States and seats of learning have qualified by a yearly subvention to place a "Studien-Tisch" at the disposal of representatives of their respective nationalities. Cambridge, Oxford, the Columbia University of New York, the Smithsonian Institution in Washington, to say nothing of the British Association for the Advancement of Science, are among those annual subscribers, insomuch that this "festa" was not that of Germany or Italy alone, but that of the whole world of inductive research in its most fundamental and far-reaching department. The proceedings began with the reading of congratulatory telegrams from the King of Italy (represented on the occasion by the Minister of Public Instruction, Signor Gianturco), from the Emperor William (represented by the German Ambassador von Bulow), from the Grand Duke of Saxony, the Ministers von der Bruck, Bötticher, and Bosse, the rectors of the Universities of Munich and Strasburg, the Zoological and Botanical Societies of Austria, Russia, and Holland, and of numerous other scientific bodies, European and American. First to speak was the Senator Francesco Todaro, Professor of Anatomy in the Roman University (who appeared for the Accademia dei Lincei, the Italian analogue of the Royal Society), who tendered Italy's welcome to the assembled visitors; then came Professor Eisig, who spoke for the "Stazione Zoologica" in a similar sense. He was followed by Professor Waldeyer, representing the Berlin Academy of Sciences; and after him rose the Syndic of Naples, who, in well-chosen words, presented Professor Dohrn with an illuminated parchment conferring on him the freedom of the city of Naples. The next item in the programme was the address of Vice-Admiral Palumbo, who spoke for the Minister of Marine (Signor Brin) and the whole Italian navy, succeeded by his Excellency Signor Gianturco, who, in the name of King Humbert, conferred upon Professor Dohrn the Grand Cordon of the Crown of Italy, and nominated him Honorary Professor in the University of Naples. The thanks of Germany for these distinctions bestowed on a compatriot were then given by the Ambassador von Bulow, and then Professor Dohrn rose to make the speech of the occasion. In vivid language he gave an outline of the genesis, the growth, and the future prospects of the "Stazione"—its first inception in 1870–71 and its acquiring "a local habitation and a name" in 1872, when the Court and Government of Berlin endowed it, in perpetuity, with a yearly grant of 40,000 marks. Very touching were the allusions to the part taken by his young wife in the early days of the institution—a devotion which transferred itself, by a generous contagion, to every *alumnus* attached to its teaching. Repeated rounds of applause greeted him as he resumed his seat, acknowledging that his *più alto compenso* (his loftiest compensation) was the *apoteosi di oggi* (the apotheosis of to-day). After this the assembled company, among whom I may signalise a steadfast friend of the "Stazione," Dr. Wilhelm His, Professor of Anatomy in the University of Leipzig, made a round of the laboratories, the aquarium, and the unique collections of the Mediterranean flora and fauna, veritable *spolia opima* of biological science. A great banquet in the evening, held at the West-End Hotel, concluded the programme of a memorable day—memorable not only in the annals of research, but in the record of that international brotherhood which it is one of the subsidiary, but none the less important, functions of science to deepen and extend.

Tragic Incident at Bologna.

Professor Augusto Obici, who recently came from Modena with the highest reputation to fill the chair of Pathological Anatomy in the University of Bologna and had delivered his inaugural discourse to a delighted audience of students and professional colleagues, has committed suicide by throwing himself from the Aposa bridge into the river beneath, a distance of a hundred feet. Death was immediate. Professor Obici was just thirty years of age and had been suffering from profound neurasthenia.

April 17th.

Obituary.

CHARLES HIGATT TENCH, B.A., M.D. DUB., L.R.C.S. IREL., L.M.

THE death of Dr. C. H. Tench of Reading is announced, the deceased having been suddenly struck down by an attack of cerebral hæmorrhage upon April 9th. He was in his fortieth year and had been in practice at Reading for some fifteen years, being at the beginning of his career in partnership with his cousin, Dr. Phillips Conn. He afterwards set up in practice for himself in Oxford-road, Reading, and gained the esteem and affection of all with whom he came in contact. The funeral took place on April 13th at St. Giles's Church, and was largely attended by private friends and relatives, as well as by most of the medical colleagues of the deceased in the city and district.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The death of the following eminent foreign medical man is announced:—Dr. Schaker Sakaki, Extraordinary Professor of Psychiatry and Nervous Diseases in the University of Tokio, from a laryngeal affection, at the age of forty-one years.

Medical News.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the Second Examination for the degree of Bachelor in Medicine at the College of Medicine, Newcastle-upon-Tyne, in April, the following candidates satisfied the examiners:—

Anatomy, Physiology, and Materia Medica.—Second-class Honours: Herbert George Harris, St. Bartholomew's Hospital; Claudia Anita Prout Rowse, London School of Medicine for Women; Solomon Cross and Maurice Jacobs, College of Medicine, Newcastle-upon-Tyne; Selina Fitzherbert Fox, London School of Medicine for Women; Robert Walker, St. Bartholomew's Hospital; Hedda Alström, London School of Medicine for Women; Francis Ward Crossman, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital, and Harold Robert Dacre Spitta, St. George's Hospital. *Pass List:* Laurence James Blandford, College of Medicine, Newcastle-upon-Tyne; Edleston Harvey Cooke, St. Thomas's Hospital; George Oswald Morrell Dickenson, Henry Eggleston, Harold Ferens, Charles Thomas Holmes, and Ernest Inman, College of Medicine, Newcastle-upon-Tyne; Margaret Joyce, London School of Medicine for Women; Ernest George Klumpp and Gilbert Smith, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Eliot Swainston, Fred Stuart, Edward Norman Threlfall, and David Henderson Weir, College of Medicine, Newcastle-upon-Tyne; Frederick Day Welch, Guy's Hospital; and Edgar Sheldon Wilkinson, St. Bartholomew's Hospital.

FOREIGN UNIVERSITY INTELLIGENCE.—*Budapest:* Dr. Alexander v. Korányi has been appointed Extraordinary Professor of Internal Medicine; Dr. G. Fodor, Dr. B. Imródy, and Dr. F. Tauszk have qualified as *privat-docenten* of Internal Medicine, and Dr. G. Rigler as *privat-docent* of Hygiene.—*Jurieff (Dorpat):* Dr. Wilhelm Koch, Professor of Surgery, is about to retire, thus still further diminishing the remaining body of German professors, who are being rapidly replaced by Russians.—*Ghent:* Dr. F. van Imschoot has been appointed Extraordinary Professor of Clinical Surgery.—*Kazan:* Dr. J. Praxin has been appointed Extraordinary Professor of Surgery.—*Lemberg:* Dr. L. A. Gluzinski has been appointed Professor of Internal Medicine.—*St. Petersburg Military Medical Academy:* Dr. J. B. Pavloff has been appointed Professor of Physiology; Dr. Michailoff, Assistant in Professor Sirotinin's clinic, has qualified as *privat docent* of Internal Medicine.—*Tomsk:* Dr. Romanoff has been appointed Extraordinary Professor of Pathological Anatomy.—*Strasburg:* Dr. Ernst Levy has been appointed Extraordinary Professor of Internal Medicine.—*Vienna:* For the first time a lady, the Baronin Posanner, has been admitted to the degree of Doctor of Medicine.—*Warsaw:*

Hosted by Google

Dr. W. Brodowsky, Professor of Pathological Anatomy and the senior member of the professorial staff, is about to retire.

METROPOLITAN HOSPITAL.—The annual dinner in aid of the Metropolitan Hospital, Kingsland-road, was held on March 18th at the Hôtel Métropole, the Lord Mayor being in the chair. It was stated that there was at that time a sum of about £5000 owing to tradesmen and that the building was mortgaged for £10,000. The hospital had accommodation for 160 in-patients, but the present state of the finances did not allow of more than about eighty beds being used.

PLYMOUTH ROYAL EYE INFIRMARY.—The committee of this institution have just issued an appeal for funds in order to provide a new building, the present one being inconvenient and unsuitable. The committee have the option of a favourable site at Mutley, and their architects have already prepared plans. The estimated cost of the land and buildings is about £12,000. This work, they think, would be an excellent commemoration of the sixtieth year of the Queen's reign.

UNIVERSITY COLLEGE HOSPITAL.—The annual meeting of University College Hospital was held in the institution on March 19th, Lord Monkswell presiding. It was announced that Sir Blundell Maple, M.P., had given a munificent donation of £100,000 for the purpose of re-building the hospital. None of this sum, however, was available for ordinary expenditure, and the state of the finances was a cause of much anxiety to the committee, the accumulated excess of expenditure over income having been £17,500 at the end of the year.

FOOTBALL CASUALTIES.—On the 10th inst. a member of the Stoke Club, while playing centre forward for his club a few miles out of Thame, sustained a compound fracture of his leg.—During a match between local Volunteers and Shop Assistants at Tamworth on Good Friday, a member of the former team, aged twenty-one years, received internal injuries, from which he died the following day.—In the course of a match at Bedford on Saturday last, betwen Bedford and Abercarn, two players had to be carried off the field to the infirmary, one of the Welsh three-quarters fractured his clavicle, and one of the Bedford forwards broke two of his ribs.

PRESENTATIONS TO MEDICAL MEN.—On the 2nd inst., at a complimentary dinner at Blanchard's Restaurant, Regent-street, London, Mr. Charles R. Walker, M.R.C.S Eng., L.R.C.P.Lond., M.D.Brux., of Leytonstone, was presented with a very handsome ornamental clock as a memento of good wishes and esteem by his brother practitioners and old friends in Leytonstone and district, on the occasion of relinquishing his practice there.—Dr. R. F. Smith, on his leaving Cork, was the recipient on the 5th inst. of an address, pocket surgical case, gold chain, and writing album from his fellow-students of the Queen's College, as tributes of esteem.—Mr. A. Simpson, M.D. Edin., of Perth, received, on the 1st inst., from the members of the St. Andrews Ambulance Association, a handsome cairngorm mounted in gold bearing the inscription, "St. Andrews Ambulance Class to Dr. Simpson, 1897," as an acknowledgment of his gratuitous lectures to the class.—Mr. John Lloyd-Davies, M.R.C.S. Eng., L.R.C.P. Lond., the representative of the Dowlais Iron Company's medical staff at Penydarren, near Merthyr Tydvil, was at a public meeting on April 1st presented with an illuminated address and a purse containing forty sovereigns as a mark of appreciation of his services.—Mr. L. L. Bulkeley Williams, M.B., C.M. Glasg., of Sidmouth, on the occasion of his leaving that town, was entertained by his friends and patients at a dinner and presented with a silver punch bowl in appreciation of his services, public and professional, during his residence in Sidmouth.—The members of the St. John Ambulance class at Blagdon, Somerset, have recently presented Mr. T. Oates Halliwell, M.R.C.S., L.R.C.P. Lond., of Blagdon, with a portable galvanic battery as a mark of their appreciation of his services as honorary lecturer.—On the 8th inst. Mr. Thomas Scott Brodie, M.B., C.M. Glasg., of Houston, Renfrewshire, on the occasion of distributing the proficiency certificates of the combined ambulance classes (ladies and gentlemen), held each winter under the auspices of the St. Andrews Ambulance Association, was the recipient of a beautiful marble timepiece in recognition of the valuable services he had rendered to the classes.

EPIDEMIC OF MEASLES AT WELLS.—At the April meeting of the Wells (Somerset) town council the medical officer of health reported that 320 cases of measles had been notified during the quarter, but the outbreak was now rapidly subsiding.

ISOLATION HOSPITALS IN GLAMORGANSHIRE.—Plans have been prepared for additional isolation hospitals in Glamorganshire, and it is expected that thirteen new ones will be erected within the year, making twenty-one altogether.

THE death of a very successful quack is announced in Berlin by suicide from religious mania. He founded a sort of quack society and persuaded so many people to believe in his nostrums that he is said to have made from £6000 to £12,000 a year.

MEDICAL MAGISTRATE.—On the recommendation of the Lord-Lieutenant, the Lord Chancellor has placed Mr. Wm. Makeig Jones, of Wath-upon-Dearne, Rotherham, on the Commission of the Peace for the West Riding of Yorkshire.

WE are asked by Mr. George Stoker to state that the "Oxygen House" has been moved from St. George's-square to No. 2, Fitzroy-square, W., where demonstrations will be given on Tuesdays, Thursdays, and Saturdays at 4.30 P.M. till further notice.

THE POLLUTION OF THE RIVER DEE.—A conference representing the county councils of Cheshire, Flintshire, Denbigh, Shropshire, and Merionethshire was held recently, and a recommendation was passed in favour of forming a joint board for enforcing the Rivers Pollution Act (1876) throughout the entire watershed of the Dee.

NOTTINGHAM FREE HOSPITAL FOR SICK CHILDREN.—The annual meeting of the Nottingham Free Hospital for Sick Children was held in the Exchange Rooms, Nottingham, on April 7th, Lord Henry Bentinck, M.P., presiding. The report stated that 449 children had passed through the wards, and that there were 2292 out-patients who made over 9000 attendances. The accounts showed an accumulated deficiency of £170.

CARDIFF.—Dr. Williams, the medical officer of health of the Glamorganshire County Council, in the course of a lecture recently given at Cardiff, said that a fitting way to commemorate Her Majesty's long reign would be to establish in Cardiff an institute of preventive medicine in which bacteriological work and analyses of water and food supplies might be undertaken. The Glamorganshire County Council had lately promised £3000 for this object, and he hoped that the corporation of Cardiff might even do better.

BIRKENHEAD MEDICAL SOCIETY.—At a meeting of this society on April 9th, Dr. R. Sydney Marsden, President, being in the chair, Mr. Vacher read a paper on an Outbreak of Typhoid Fever in a large public institution, having in all about 700 inmates. From March 10th to 15th, 1896, seventeen persons manifested signs of the disease, and the inference was that they were all infected at or about the same time and probably from a common source. On inquiry it was found that a nurse attendant who had leave of absence twice a week or oftener, had complained of being feverish and unwell on Feb. 18th, and had gone home on the 26th. Following up this case it was found that it was without doubt one of typhoid fever. Attention was directed to the disposal of this patient's excreta, and evidence was forthcoming that some at least during the early days of her illness had been emptied into a contiguous ashpit. Now the pressure in the water mains at the institution was off during the night, and one of the hydrant boxes was in front of the room in which this patient was located. The position of this hydrant box was at the side of the road on which ashes from the ashpit had been spread to mend it. The box was below the level of the road, and on taking it up there was proof that water from the road had been running into it. As the ball would fall during the night it was obvious that water from the road which had leaked into the box would get into the main. It appeared, therefore, that certain portions of the water used for drinking became infected by means of some of the excreta from the initial case which had first been deposited in an ashpit and then on a road near a hydrant box.—A discussion ensued, in which Mr. Stansfield, Dr. Pinkerton, and the President took part.—Mr. Vacher replied.

BIRMINGHAM GENERAL HOSPITAL.—The annual meeting of the Birmingham General Hospital was held on March 17th, the Lord Mayor of Birmingham presiding. The report showed that during last year there were 4486 in-patients and 52,203 out-patients. The financial statement mentioned that the banking account was overdrawn to the extent of £1450. The present hospital, which contains 271 beds, was opened by Dr. John Ash with forty beds in 1779, but will not be occupied much longer, as the new hospital will be opened by Princess Christian on behalf of the Queen on July 7th. Of the early physicians and surgeons Dr. Male was on the staff for thirty-six years and Mr. Robert White for forty-four years, while the three Drs. Johnstone, two brothers and a nephew, were honorary physicians for an aggregate period of eighty-five years. A special appeal for funds for the new hospital is to be made.

ANNUAL REPORT OF THE SYDNEY HOSPITAL.—The fifty-second annual meeting of the subscribers to the Sydney Hospital, New South Wales, was held on Feb. 24th. The report showed that the number of cases in hospital on Dec. 31st, 1896, was 271, the percentage mortality on admission 11 3, the average number of beds occupied 275 9, and the average cost per bed £61 2*s.* 2*d.* The total number of operations performed during the year was 1703. The out-door department during the past year had been worked on a more systematic manner, the circumstances of all applicants for out-door relief were inquired into by a special officer, and patients able to contribute the sum of 1*s.* were asked to do so. The Moorcliff Eye Hospital had been thoroughly repaired and renovated. The chairman stated that during the twenty years he had been a director of the institution it had never been in such a good financial position as it was now.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of directors of the society was held on April 14th, Mr. Christopher Heath, Vice-President, being in the chair. Three new members were elected and the deaths of five members reported. The death of a widow was announced who had received £35 per annum since 1886. Applications for grants were read from fifty-one widows, eleven orphans, and five recipients from the Copeland Fund, and a sum of £1210 was recommended to be divided among them at the next court. An extra grant of 24 guineas was made to an orphan to enable him to learn bookkeeping, &c. The expenses of the quarter amounted to £60 7*s.* The directors nominated for election at the annual general meeting the following gentlemen to fill the vacancies among the vice-presidents and directors, viz., Dr. Wilks, Dr. Pollock, and Mr. Felce to be vice-presidents; Dr. Blandford, Dr. Ogle, Dr. Brodie, Dr. de Havilland Hall, Dr. Slight, Dr. James Miller, Mr. Lovett, and Mr. Day as directors. The annual general meeting was fixed to be held on May 19th, at 5 P.M.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The seventh meeting of the session was held on April 14th in the Medical Library of University College, Dr. Aust Lawrence being in the chair.—Dr. Shaw showed a case of Melancholia with Catalepsy.—Mr. Morton showed a patient (and specimen) from whom the Scapula had been removed for Sarcoma.—Dr. B. Baron showed a patient with Lupus of the Nostrils and Throat; also a patient with extensive Web Formation, partially shutting off the naso-pharynx from the mouth.—Dr. P. W. Williams remarked on the cases.—Dr. P. W. Williams showed a patient with Coarse Tremor of the Vocal Cords in a case of Disseminated Sclerosis, and a specimen of Aortic Aneurysm.—Mr. Munro Smith read notes on a case of Abdominal Section in a Python.—Dr. Harrison made some remarks on the case.—Dr. W. H. Newnham read a paper on a case of Puerperal Eclampsia successfully treated by Rapid Delivery.—Dr. W. C. Swayne, Dr. Aust Lawrence, Mr. S. H. Swayne, and Dr. J. G. Swayne commented on the paper.—Mr. J. Lacy Firth read a paper on two cases of Respiratory Paralysis from Intra-cranial Pressure, ending in death.—Dr. Williams, Dr. Waldo. Dr. Fisher, Dr. Aust Lawrence, Dr. Randall, Dr. W. C. Swayne, and Mr. S. H. Swayne remarked on the paper.—Dr. Michell Clarke read a paper on a case of Acute Miliary Tuberculosis treated with Anti-streptococcic Serum on account of the presence in the blood during life of streptococcus pyogenes albus.—Dr. Fisher, Dr. Shingleton Smith, Dr. P. W. Williams, Mr. Morton, and Dr. Rogers made remarks on the paper.

THE ROYAL INSTITUTION OF GREAT BRITAIN.—Lecture arrangements for after Easter include three lectures on Tuesdays, May 25th and June 1st and 8th, by Ernest H. Starling, M.D., dealing with the Heart and its Work; and three lectures on Thursdays, May 27th and June 3rd and 10th, by Professor Dewar, the subject of which will be Liquid Air as an Agent of Research. The lecture hour will be 3 o'clock. On Friday evening, May 21st, Lord Kelvin will deliver a lecture on Contact Electricity of Metals, and on May 28th Professor H. Moissan will discuss the Isolation of Fluorine.

DIPHTHERIA IN LONDON.—In the four-week period ended on March 27th, there were notified 902 cases of diphtheria in London, all the sanitary districts being invaded. This total is slightly less than that of the February period, which was 916, and is a satisfactory decline from the totals of preceding periods. The 902 cases notified yielded a weekly average of 226. In five districts there were 335 cases notified, or more than one-third of the gross number for the whole of the county. In six other districts there were only 10 cases notified. The weekly average in February was 229; there were 299 cases in four of the districts, whilst five other areas had only 9 cases amongst them. In the March period there were 176 deaths registered in London, against 185 in the February period; whilst the per case mortality in March was 19 5 per cent. of the notifications, as against 20·2 in February. In the two weeks that followed the March period the mortality data continued to be very satisfactory. In the week ended April 3rd there were 41 deaths in London, a number which was 10 in excess of the corrected decennial average for the twelfth week of the period 1887–96. The deaths in the three preceding weeks had been 53, 37, and 43 respectively. Of the 41 deaths in the week ended the 3rd instant, there were 40 of persons aged under twenty years, 37 being of young children aged from one to five years. The admissions to hospital in the week numbered 93, against 97, 113, and 91 in the preceding three weeks. There remained under treatment at the close of the week 777 patients. In the succeeding week there was further decline in the number of registered deaths from diphtheria in London, these numbering only 23, and being 9 below the corrected decennial average for the thirteenth week of the year. All were of young persons aged under twenty years. Camberwell was credited with 5 deaths, Mile End Old Town with 3, and Poplar, Lambeth, Bermondsey, and Wandsworth sanitary areas respectively with 2 deaths. The admissions to hospital were 103, and the total number of patients remaining under treatment on Saturday, April 10th, was identical with that of the preceding week—namely, 777. In the week ended April 3rd there were 10 deaths registered from the disease in the Outer Ring, of which half were in the Hendon district, whilst in the next week the total in the Outer Ring rose to 14, of which 6 were in West Ham, and 2 in the Brentford, the Hendon, and the Edmonton districts respectively.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BENNETT, NORMAN G., B.A., B.C. Cantab., L.D.S. Eng., has been appointed Assistant Dental Surgeon to the Dental Hospital of London.

BERRY, H. P., M.B. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Grantham Town Council.

BOND, FRANCIS THOMAS, M.D. Lond., M.R.C.S., F.R.S.E., has been re-appointed Medical Officer of Health by the Chipping Sodbury Guardians and Council.

BOYD, ROBERT, M.B., C.M. Glasg., has been appointed Senior House Surgeon to Huddersfield Infirmary, vice G. W. K. Crosland, resigned.

BURGESS, R., M.B., C.M. Aberd., has been appointed Third House Surgeon to Huddersfield Infirmary, vice R. C. Jameson, resigned.

BURRELL, A. W., M.D., L.R.C.P. Lond., M.R.C.S., has been appointed a Clinical Assistant at St. John's Hospital for Diseases of the Skin, London.

BYFORD, W. F., L.R.C.P. Lond., M.R.C.S., has been appointed, *pro tem.*, Assistant Medical Officer for the Nottingham Workhouse.

TUESDAY (27th).—ROYAL INSTITUTION.—3 P.M. Dr. T. Anderson: Volcanoes. (Tyndall Lectures.)

WEDNESDAY (28th).—THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—3 P.M. Mr. W. B. Bryan (conducted by): Inspection and Demonstration at the East London Water Works, Lea Bridge.

THURSDAY (29th).—THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Mr. C. Mason: Scavenging, Disposal of House Refuse.

FRIDAY (30th).—ROYAL INSTITUTION.—9 P.M. Prof. J. J. Thomson: Cathode Rays.

SATURDAY (1st).—THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—Mr. J. E. Worth (conducted by): Inspection and Demonstration at the Sewage Outfall Works, Barking.

ROYAL INSTITUTION.—5 P.M. Annual Meeting.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

THE CREMATION SOCIETY OF ENGLAND.

DURING the year 1896 there were 137 cremations carried out at Woking, as compared with 150 in 1895, and 125 in 1894. There are at the present time three crematoria open in England and Scotland in addition to the one at Woking which belongs to the Cremation Society of England. These three are respectively at Manchester, where fifty-five cremations took place during 1896; at Glasgow, where there were eleven cremations; and at Liverpool, where two cremations have been performed. The crematorium at Liverpool was only opened in the middle of September, 1896, the inaugural ceremony being performed by the Earl of Derby, who was Lord Mayor of Liverpool at the time. It immediately adjoins, and communicates with, the Anfield Cemetery; the site and crematorium have cost some £7000 and are the property of the Liverpool Crematorium Company, Limited. The published accounts of the Cremation Society of England show for 1896 an income of £820 and an outlay of £740. The full charge for cremation at Woking is £5, the extras being the local clergyman's fee of 1 guinea, if it is desired that he should officiate at the service, and a payment of about 10s. for the attendance of bearers if undertakers' assistants are not brought from London. Unless it is intended to hold a funeral service in public the body should not be placed in a heavy or costly coffin, a light pine shell is the best receptacle for the purpose of cremation. The annual report of the society makes sympathetic reference to the late Sir Spencer Wells, who was one of its founders and whose remains were cremated at Woking. The offices of the society are in New Cavendish-street, Portland-place.

C. B. cannot be advised to break an agreement into which he has entered. His solicitor can tell him how far the contract is binding, or, as he phrases it, "legal." If he is advised that he has contracted himself out of certain facilities he must acquiesce in the consequences of his own act unless he can prove that he was induced to sign by misrepresentation. The fact that he did not understand what he was doing when he signed is of no legal import.

Dr. J. Ross.—Under the circumstances detailed by our correspondent we do not see wherein the necessity for the inquest existed, but the coroner's reason might, nevertheless, be very sound.

THE CRIME OF ABORTION IN THE UNITED STATES.

DR. H. P. BEIRNE, Professor of Natural Science, Corpus Christi Lyceum, Galesburg, Illinois, writes a letter to the *New York Medical Record* of April 10th, 1897, lamenting that American families which used to number eight or ten now consist of three or only two, and attributing it, not to any natural difference, but to moral differences in the estimate of such questions. He instances one woman in a city with a dozen churches and 20,000 inhabitants, who boasted that she had had 100 cases of successful abortions.

"DR. RENTOUL'S EXPENSES FUND."—FIFTH LIST.

To the Editors of THE LANCET.

SIRS,—It is intended to close this fund next week, when a statement will be made as to the exact amount subscribed. I may say now that after deducting expenses we are about £9 short of the sum asked for at first. As several practitioners who have tacitly promised to subscribe have as yet not forwarded their donations, I beg that they will send them on without delay and allow me to say next week that the sum desired has been subscribed.

I am, Sirs, yours faithfully,

ALFRED COX, M.B. Durh., Hon. Sec. and Treasurer.

Gateshead, April 20th, 1897.

Dr. W. T. Greene.—We thoroughly agree with our correspondent that there ought to be some way of checking the open incitements to immorality and even to the crime of abortion that are furnished by certain advertisements. We have often referred to this matter in the columns of THE LANCET, but the remedy is in the hands of the public. If the public would complain in sufficient numbers to the managers of the papers inserting these filthy advertisements, that either they must lose such advertisers or their readers, the advertisements would cease.

IMPROPER ADVERTISEMENT.

WE have received a copy of the *Louth Advertiser* wherein an advertisement of an optician is supported by signed testimonials from an "M.A., M.D., M.R.C.S.," and a "Surgeon-Major, Army Medical Reserve, &c." We cannot suppose that these gentlemen knew the commercial use to which their testimonials would be put, and advise them to take means to prevent the optician giving them this unfortunate publicity.

AN INTERESTING SOUVENIR.

MESSRS. MARCUS WARD AND CO., Limited, are about to publish a plate depicting the Queen at the Coronation in 1837 and as she appears at the present day. We are asked to announce that the profit realised by the sale of the publication will be handed over to the Queen's Jubilee Institute for Nurses.

DISINFECTION AFTER ANTHRAX.

To the Editors of THE LANCET.

SIRS,—Perhaps some of your readers could give me some information as to the best way of thoroughly disinfecting a cow stable after anthrax. About three weeks ago a farmer near here lost a young cow, which luckily was kept by itself, from the above disease, and the stable it was in was very thoroughly lime-washed and some perchloride of mercury (1 in 1000) used to wash down the floor, but the other day I made a plate cultivation from the soil and dust between the bricks which form the floor of the cow-stable and in a day or two found colonies of anthrax bacilli. I am anxious, therefore, to know the best way to disinfect a stable so as to avoid all risk for the future. I may say that there had been no previous case on the farm within the memory of the present tenant or his father, also that every precaution was taken to avoid spilling any blood when the beast died.

I am, Sirs, yours faithfully,

April 13th, 1897. M. O. H.

*** It will be found a difficult matter to disinfect *in situ* the soil between the bricks, and it would probably be the safest course, having regard to the tendency of the anthrax bacillus to multiply and to form spores in polluted earth, if the floor of the stable were taken up and relaid with new bricks set in cement; and this course would be especially indicated if the floor be at all dilapidated. Care should, of course, be exercised by the workmen in removing the bricks and soil, both of which should be subsequently disinfected and safely disposed of. If entire reconstruction is impracticable the earth from between the bricks might be as far as possible removed, and the intervals, after being saturated with a strong solution of perchloride of mercury or crude carbolic acid, be subsequently filled in with good cement, the surface of the bricks being well covered with the same material. Planing the manger to some depth would appear to be a useful precaution.—ED. L.

AN UNUSUAL CASE.

To the Editors of THE LANCET.

SIRS,—I have been in active general practice for more than thirty years, and of course have met with many cases of intestinal obstruction; in some of these cases the obstruction has been caused by very peculiar articles, but the following case is unique as far as my experience is concerned. Last week I was called to a middle-aged woman, who was suffering from all the symptoms of complete obstruction, and after making the usual examination for hernia, &c., the turn came to the rectum. This I found completely blocked with an immense mass of solid matter on which it was difficult to make any impression with the finger; however, after about half an hour's work I succeeded in excavating a portion of the mass, which on examination proved to consist of wool firmly welded together with fæcal matter. After further work I managed to get the tube of an enema syringe partly through the mass, and injected about three pints of warm water. This made matters worse, for it washed away the fæcal matter, leaving behind a firm mass of nothing but wool, which appeared to fill the whole pelvis. To make a long story short, after three "sittings" at intervals of twenty-four hours I succeeded in removing the whole of the wool and obtaining an action of the bowels with relief of all the symptoms, the quantity of firmly matted wool being larger than my doubled fist, both patient and medical man being considerably "pumped" after each operation. The cause of the whole trouble was that the patient had been partaking largely of lambs' tails ever since the advent of the lambing season. The lambs' tails, instead of being skinned as, I believe, is usual before they are cooked, had only been singed and then baked, thus leaving, probably, much of the wool adherent to the flesh. I could not arrive at any conclusion as to the number of tails eaten, but I suppose they must have been very numerous. The patient declares that she will never eat another tail as long as she lives; but I think very likely about this time next year she will forget her troubles and again indulge in this luxury. If she does so without removing the wool, all I can say is, "May I not be there to see." It would be interesting to me to know if this cause of obstruction has been met with before.

I am, Sirs, yours faithfully,

Kettering, April 18th, 1897. J. WINTER DRYLAND.

B.—It seems to us a pity that our correspondent did not write to A. on the matter, as it is a pity that A. has seen in the omission to do so evidence of serious misconduct. The whole affair is so trivial that surely the parties concerned are not going to allow it to cause a breach in their professional relations with each other.

Juvenis.—We do not know where the literature on the subject can be procured, but there is a society existent for the propagation of the tenets.

R. D. (Westbourne) has omitted to enclose his name and address.

The Lumleian Lectures

ON

SOME PROBLEMS IN CONNEXION WITH APHASIA AND OTHER SPEECH DEFECTS.

Delivered before the Royal College of Physicians of London on April 1st, 6th, and 8th, 1897,

BY H. CHARLTON BASTIAN, M.A., M.D. LOND., F.R.S.,

CENSOR OF THE COLLEGE; PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

LECTURE III.[1] (*concluded from p. 1137*).

Delivered on April 8th, 1897.

(5) DEFECTS RESULTING FROM ABNORMAL CONDITIONS OF THE LEFT VISUAL WORD-CENTRE.

THERE is not the same variety in the defects of speech caused by disease of the visual word-centre that is to be met with as a result of disabilities in the auditory word-centre. This is apparently due to the fact that in the great majority of persons voluntary revival of words occurs primarily in the auditory word-centre, while the visual word-centre is called into activity mainly by stronger stimuli—either by those coming to it through associational fibres or by still stronger incitations that come directly from without. It is only in comparatively rare cases, as we have seen, that the visual word-centre takes the place occupied in the great majority of individuals by the auditory word-centre, as the seat in which words are primarily revived in silent or in spoken thought. Consequently the speech defect known as "amnesia verbalis" occurs almost only as a result of a lowered functional activity in the auditory word-centre, and only in extremely rare cases (where the individual is a very strong "visual") as a result of mere lowered activity in the visual word-centre. Since a volitional stimulus is weaker than that which comes through an associational channel from a centre strongly aroused, and weaker still than that which comes to the centre directly from without, and since a lowered nutrition or diminished molecular mobility of a centre from any cause might lead only to a failure in the centre to respond to the weakest stimuli, it is to be expected that such results in relation to language would show themselves only in connexion with the centre accustomed to respond to such stimuli (namely, the auditory word-centre), and would be almost absent in connexion with the visual word-centre.

Consequently we know next to nothing about the effects of mere functional degradation in the visual word-centre—that is, of slight disabilities such as when occurring in the auditory word-centre are productive of the various degrees of amnesia verbalis already described. All that can be said is that when such functional degradation of the visual word-centre is present it would (*a*) in the rare case of the patient being an extremely strong "visual" of itself tend to produce amnesia verbalis, as was seen in a patient under the care of Charcot, whose case is referred to by Ballet[2]; or (*b*) even in an "auditive" tend greatly to aggravate any disability that may have been caused by a co-existing defect in the auditory word-centre, and also to hinder recovery therefrom; further (*c*) that where the functional defect involves both word-centres the amnesia ought to be more than usually bad and probably associated with more or less of paraphasia.

Effects produced by the destruction of the left visual word-centre.—We have to pass, then, at once to a consideration of the effects produced by destruction of the left visual word-centre, which is now generally supposed to be situated in the angular, and possibly in part of the supra-marginal, convolution. These effects will be found to vary in different individuals, just as variation was found to be the case when we had to do with the results of lesions in the left auditory word-centre.

One important difference between the effects of lesions of the visual word-centre as compared with those following upon lesions of the auditory is that speech is very little, if at all, interfered with. There is no well-marked aphasia or paraphasia, only a very slight amount of paraphasia in some of the cases.[3] That there should at times be such slight disturbance of speech is not to be wondered at if we bear in mind the close functional relationships of the visual and the auditory word-centres, and how easily therefore the functions of the latter may be disturbed by a lesion in the former.

It is often found that word-blindness is associated with right-sided homonymous hemianopsia—that is, on the same side as paresis of the limbs—for there is often no complete hemiplegia in these cases. The hemianopsia is generally due to destruction of the optic radiations of Gratiolet; but where the lesion is quite limited to the cortex these fibres will not be involved, so that hemianopsia is not a necessary accompaniment of word-blindness.

Agraphia also is a symptom sometimes present and sometimes absent in cases of word-blindness. The presence or absence of this symptom is, however, of much more fundamental importance than the presence or absence of hemianopsia. It is best, in fact, to divide cases of word-blindness into two categories—namely, (*a*) cases in which the word-blindness is associated with agraphia, and (*b*) cases in which there is no agraphia. In the latter group it is found that the individuals can write as well with the eyes closed as when they are open, and further that they are, after a brief interval, unable to read what they themselves have written.

(*a*) In the cases where agraphia is present it is commonly found that such patients are capable of writing their names correctly, although they can write nothing else. The signature is an emblem which may, by reason of its familiarity, be executed by the cheiro-kinæsthetic centre with the smallest amount of prompting; and it would appear that this prompting may come from the common visual centre in cases where the left visual word-centre is destroyed. Similarly a word-blind patient may be able to recognise his own name when he sees it, though apart from this there may be complete alexia. As Déjerine says[4]: "He recognises it by its general form, by its physiognomy, and not by the assemblage of letters of which it is composed"—just, in fact, as he would recognise a geometrical figure or any other drawing. Differences of degree are, however, met with in word-blindness. In some cases, though the patients are unable to recognise single words (word-blindness), they can recognise individual letters; whilst in others not even letters can be recognised (letter-blindness). These two forms were distinguished by Kussmaul, though he sought to make a more radical distinction between them—believing that they represented differences in kind rather than of degree. All intermediate forms, however, may be met with. Sometimes patients will recognise certain letters and not others; and in one case recorded by Batterham vowels only were recognised.

In illustration of this first group of cases, where word-blindness is associated with agraphia, I will quote one of a very typical character that has been reported by Déjerine.[5]

CASE 32.—A man, aged sixty-three years, seven years previously had a slight attack of right hemiplegia, not accompanied by speech troubles, which at the time of his entering the Bicêtre (Feb. 12th, 1890) had almost completely disappeared. Soon after his admission he found one morning that he could no longer read his newspaper. On examination it was ascertained that there was no trace of word-deafness: he easily understood all questions. He was unable to understand either print or handwriting, and could not even name a single letter of the alphabet. On the other hand, he could recognise his name and could name all objects shown to him. Right lateral hemianopsia was believed to exist. There was paraphasia both in his spontaneous speech and in his repetition of words, so that it was sometimes difficult to understand what he said. When asked to write he held the pen most awkwardly and could write nothing but his name, and that so badly as to be scarcely recognisable; and whether he attempted to write spontaneously, from dictation, or to copy he wrote only his own name, "Séjalon," in an indistinct fashion. On March 10th the initial paraphasia had almost completely disappeared, so that he could readily give particulars concerning his former life and his present condition. His writing was as bad as before, but he held the pen much better. He could not write a single word spontaneously or from dictation, nor could he copy—he made mere meaningless strokes only; but he could write from dictation a numeral or a number composed of not more than two figures. There was complete alexia, as before; he recognised his own name, but nothing else. On Nov. 5th, 1890, the

[1] Lectures I., II, and part of III. were published in THE LANCET of April 3rd, 10th, and 24th, 1897, respectively.

[5] Loc. cit., p. 197.

Hosted by Google

word-blindness was slightly less. He could then recognise "c" and "g" of the alphabet, but no other letters. He could not make out any word, but he recognised and pronounced numerals and numbers of not more than two figures. The agraphia was as complete as before, both for spontaneous writing, dictation, and copying. Death occurred on Nov. 20th, 1890, and at the necropsy a focus of softening having "the diameter of a five-franc piece" was found occupying the inferior three-fourths of the angular gyrus, all the rest of the cortex, including the foot of the third and also that of the second frontal convolution, being absolutely intact. Section of this left hemisphere showed that the softening extended inwards in a wedge shape as far as the posterior cornu, destroying the greater part of the optic radiations of Gratiolet. In the right hemisphere two small foci of softening of the size of a small nut were found—one in the putamen, the other in the anterior part of the thalamus, which destroyed by their union the genu of the internal capsule. (Figures of the lesion in the left hemisphere were given.)

The absolute nature of the agraphia in this case is a noteworthy feature, and may perhaps be accounted for in part by the fact that writing was a comparatively unfamiliar exercise to this man, who was a mere day labourer. Damage to the visual word-centre under such circumstances might be expected to produce its maximum results, while a similar lesion in the case of an educated man much accustomed to write might lead either to no agraphia or to a much less pronounced form of this defect. Another point of interest is the temporary nature of the paraphasia that was at first set up as a consequence of this lesion limited to a part of the angular gyrus. We can only conclude, therefore, that it was due to a sympathetic disorder established for a time in the contiguous auditory word-centre. A third point of interest is to be found in the strict localisation of the lesion to the angular gyrus and its sufficing to produce complete alexia with agraphia.

Another very similar case, and almost equally valuable, has been recorded by Sérieux,[6] of which the following is an abstract.

CASE 33.—A woman, aged seventy-three years, entered the asylum of Ville-Evrard on Sept. 29th, 1891. At the first examination it was ascertained that the patient heard and comprehended all questions well, but that there was some amount of amnesia verbalis. Reading and writing were impossible, although vision was good and she could recognise surrounding objects. After a time, being troubled by her inability to write, she practised much with her pen. At first she could only copy the letters whose outline is most simple, such as m, n, u, o, a. Her alphabet was almost composed of these letters, and they were sometimes grouped so as to give the appearance of words—such as um, aa, monon, mono, muosi. In the month of November the following observations were made: "Intelligence normal. No motor paralysis. No appreciable word-deafness. Slight paraphasia. No object blindness. Word-blindness is almost complete; she recognises a certain number of letters only. Hemianopsia absent. Agraphia is also complete for spontaneous writing, as well as for dictation and copying." On Nov. 23rd the patient had an abrupt apoplectic attack, she became comatose, and died. At the necropsy, in addition to a recent hæmorrhage into the right hemisphere, with extravasation into the ventricles, there was found one old lesion in the left hemisphere. This was a focus of yellow softening rather larger than a five-franc piece, which involved the whole of the angular gyrus and the greater part of the supra-marginal lobule. The contiguous convolutions of the superior parietal lobule as well as the posterior extremities of the first and second temporal convolutions were slightly yellowish and atrophied. All the other convolutions of this and of the other hemisphere were healthy.

Here, although the lesion was more extensive than in the last case, we find both the word-blindness and the agraphia rather less complete. The slight paraphasia, which in this case was persistent, may have been kept up by the slight degeneration of the posterior extremities of the two upper temporal convolutions. It is expressly stated that the patient did not suffer from hemianopsia, so we must conclude that the lesion was superficial and did not extend deeply enough to involve the optic radiations. Another case in which word-blindness and agraphia were produced by a patch of softening limited to the left angular gyrus has been published by Berkhan,[7] though under a very misleading title.

(*b*) In the second group of cases word-blindness is not associated with agraphia, the individuals being able to write, and as well with the eyes closed as open. As I have already said, a precisely similar group of symptoms may be produced in a totally different manner, quite independently of destruction of the left visual word-centre. These cases will be fully considered in the next section.

The effects of destruction of the left visual word-centre are liable to vary much in different individuals in accordance with their different sensorial aptitudes and different degrees of education, just as we have found the results of destruction of the left auditory word-centre to present marked differences in different cases. The results already described under group (*a*) are those which most frequently follow when the left visual word-centre is destroyed in ordinary individuals. But suppose a similar lesion to occur in a person who is a strong "auditive" but a weak "visual," and at the same time, perhaps, an educated person who has previously been in the habit of writing much. It may happen in such a person, after the stage of learning to write has well passed, that the activity of the visual word-centre may be reduced to a minimum during the execution of such acts. We have seen reason to believe that the words about to be written become nascent first in the auditory word-centre, and it seems probable that in individuals with the endowments above mentioned this centre, rather than the visual word-centre, may be the one which acts upon and coöperates with the cheiro-kinæsthetic centre, just as we have seen that in certain persons who are strong "visuals" the visual word-centre may be capable of coöperating directly with Broca's centre for the production of articulate speech. I contend, therefore, that the preservation of ability to write in cases where there has been word-blindness and where the visual word-centre has subsequently been found to be destroyed is to be explained in this way—that is, by supposing that the auditory word-centre, instead of acting, as it usually does, by rousing the visual word-centre to conjoint action, in these cases acts directly upon the cheiro-kinæsthetic centre by way of the commissure *f f* (Fig. 5).[8] The writing thus produced may be fairly good and without mistakes, though that of other patients may show defects of a paragraphic type. The handwriting itself, too, is usually larger than that which was previously customary to the patient. There is also the peculiarity that these patients can write as well with the eyes closed as when they are open, and the still further peculiarity that they cannot subsequently read what they have written except by a manœuvre which causes a stimulus to pass in the reverse way—that is, from the cheiro-kinæsthetic centre back to the auditory word-centre in the direction *f' f'* (Fig. 5). This is brought about by passing the tip of the finger over the outlines of the letters and so reading off the result. The possibility of this mode of reading by the "tip of the finger" seems to have been first noticed in a word-blind patient by Westphall.[9]

There are only two cases with necropsies that I can bring forward in illustration of this group, and unfortunately they are not very well defined cases, being rather complicated, not only clinically, but also by reason of the lesions found at the necropsy. The first of them is also, I believe, the earliest recorded instance of any such defect. It is a remarkable case that was published long ago by Broadbent.[10] The real significance of the case was not, I believe, recognised by him at the time, nor was it by myself some years afterwards when I first endeavoured to interpret it.[11] Now I think its leading peculiarities may be explained by supposing the existence of a weak condition, with lowered excitability of the auditory word-centre, together with a destruction of the visual word-centre. The case is well recorded with full details, but the essential particulars are these.

CASE 34.—The patient was a man, aged fifty-nine years, and of considerable energy and intelligence. His illness commenced early in 1870 with sickness, vomiting, and pains in the head. He was restless and delirious, and did not know his wife for a fortnight. He gradually improved, but after this attack remained unable to read either print or writing, though he could write quite well. Twelve months later he was no longer able to write voluntarily, though he could still write correctly from dictation. Soon afterwards when he came under observation he was found to be unable to read. He could see the words, but could not understand them; he could not even recognise or name single letters; the only exception to this being that he recognised his own name, whether printed or written. His voluntary speech was free except that he was amnesic and much at a loss for names. If a hand or an article of clothing, or any other familiar object, were shown him, he was quite unable to name it, while if the name came up in conversation he spoke it without hesitation. He also immediately recognised the names of common objects when he heard them. Thus, asked the colour of a card he could not give it. "Is it blue?" "No." "Green?" "No." "Red?" "Well, that's more like it." "Orange?" "Yes, orange." A square and a circle were drawn and he was asked to name either. He could not do it, but when the circle was called a square he said, "No, but that is," pointing to the proper figure. He wrote from dictation and took notes of instructions as to the day and hour of subsequent visits (which were seen to be correct), saying he was very forgetful and might make mistakes. He would be utterly

unable shortly after to read his own writing, but relied on his wife making out the notes he took. He was a vestryman, and still always attended the meetings of the vestry. He was not able to take part in the discussions as he had formerly done, but it amused him, and he added, "But I dare say I am as useful as many of them still." Broadbent adds: "He was a remarkably intelligent man, cheerful and energetic, even under his affliction. He employed in conversation a very extensive vocabulary, usually speaking fluently, sometimes stopping for want of a word (usually a name), rarely using wrong words (for which I was on the look out), the only ones I have notes of being 'soup' for 'supper,' 'nephew' for 'grandson.'" He remained under observation from May 8th to June 1st, 1879. On June 21st he had a severe apoplectic attack, due to ventricular hæmorrhage, and died within forty-eight hours. The recent extravasation had torn its way into the left temporo-sphenoidal lobe, in which there was a focus of softening, though its extent could not be ascertained in consequence of this irruption of blood. Of principal significance, however, were two old blood-clots, the size and situation of which are thus described: "One about the size and shape of an almond was closely embedded in the infra-marginal gyrus between the deep parallel sulcus on one side and the secondary small gyri on the lower wall of the fissure of Sylvius on the other, about opposite the junction of the upper third with the lower two-thirds of the descending cornu. The other was further back and on a higher level, almost exactly corresponding in situation with the posterior end of the fissure of Sylvius externally and with the junction of the descending cornu with the body of the ventricle internally; in fact, it occupied the thickness of brain substance separating the extremity of the fissure from the ventricle. It was about the size of a bean, yellow, and very tough."

It seems pretty clear that the second of these blood-clots must have been situated in the angular gyrus, whilst the first of them was situated somewhere near the middle of the upper temporal convolution, and therefore that the patient's alexia was due to destruction of the visual word-centre. Notwithstanding the damage to the upper temporal convolution and the existence of an ill-defined amount of softening in the white substance of the temporal lobe, there was obviously nothing approaching to word-deafness in this patient. The only means, therefore, of explaining his ability to write with the right hand is by supposing that his cheiro-kinæsthetic centre must have received its stimulations from the left auditory word-centre, even though the trifling verbal amnesia showed that this centre was slightly weakened.

Another case which, as it seems to me, should find its place in this group has been recorded by Osler,[12] of which the most important details are these.

CASE 35.—A man, aged seventy-two years, applied at the Philadelphia Infirmary for Disease of the Nervous System on Nov. 14th, 1888, complaining of uneasy sensations in his head. He was a healthy, vigorous looking man, perfectly intelligent, and spoke well and clearly. It was not thought at first that there was anything the matter with him beyond slight headache; but it was noticed that he had occasional difficulty in getting the word he wished, and this circumstance led to a more careful examination. For some time past he had not felt so well as usual. On Nov. 1st, while at his supper in a restaurant, he found that he could not read the daily paper. He was sure that this came on quickly, and it had been his chief annoyance, as he was an ardent politician. He had no definite headache, but complained of a diffuse uneasy sensation. Though he spoke clearly and intelligently, and uttered some sentences without interruption, replying promptly and fluently to questions and evidently understanding everything, there was very distinct speech disturbance. Thus, for some time he could not give the address of his residence. He said he knew where it was, but could not utter the words. He gave the first name of the man with whom he lived, but could not give the second. He could not name his own occupation, but said, "Keep, keep, keep; Oh, you say it for me." When told "bookkeeper," he repeated it distinctly. He occasionally misplaced words. In referring to a wetting which he had spoken of he said, "Deliberate attacks of wet dress." When a printed or written page was presented to him he did not appear to comprehend the words. The word "Philadelphia" at the head of a hospital blank he read "P, r, i, n, g, r, e, k." When told that it was Philadelphia he replied, "Oh, certainly it is, I've known it for sixty-five years." His age, "72," written on a slip of paper, he read "213." He did not recognise the words "Cleveland" and "Harrison" at the top of a newspaper column, but when they were read to him he said, "I know all about them," and began making some very shrewd observations. He could write his name, but said that since his failure to see distinctly he did so with difficulty. He wrote as well with his eyes shut as when they were open, but did so with hesitation. He wrote the name of the hospital, and the words "Philadelphia Record." He could not read the words of his name after he had written them. He named objects held before him quite readily. On examination, right lateral homonymous hemianopsia was found. For the first two weeks of his stay in the hospital there was no special change. On one occasion he wrote the word "record" when told to, but after he had written it he spelled it "freedom." On Dec. 8th he talked less freely. He spoke intelligently and plainly at first, but after a few minutes it was difficult to understand what he stated. There were no additional ocular changes. The grip in the hands was equal. He walked with a somewhat tottering gait, though there was no actual paralysis. Early in January, 1889, he became distinctly weaker, duller mentally and more restless, and on the morning of Jan. 15th he was found in a semi-comatose condition, completely paralysed in the right arm, and incompletely in the right leg. He died on the following day. At the necropsy softening was found of the left supra-marginal lobule and of the white substance of the lower part of the angular gyrus; also of the white matter of the posterior parts of the first and second temporal convolutions. There was likewise complete softening of the white matter between these convolutions and the lateral ventricle (posterior horn); while another area of softening two inches in thickness and an inch in breadth was found in the white substance of the temporal lobe, which externally touched the grey matter of the third and the base of the second temporal convolutions. Concerning the focus of softening in the substance of the left hemisphere Osler says: "Posteriorly the softening did not extend behind a line drawn across the level of the parieto-occipital fissure. The white matter of the occipital lobe was firm, and the grey matter of the cuneus was uninvolved." The right hemisphere showed no lesions.

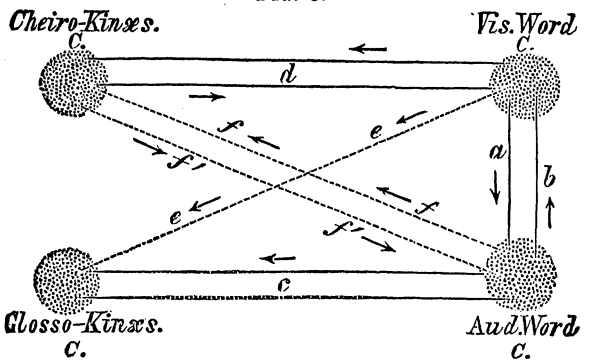
It is, of course, impossible to say how much these areas of softening may have extended during the last four or five weeks of this patient's life, when he seems to have become gradually worse; or, in other words, we cannot say how much more limited the lesion may have been during the first week that he was under observation, to which period the above detailed clinical record pertains. It seems clear, however, that the clinical symptoms were of the type now under consideration—that is to say, that there was no word-deafness, but that the patient was affected with word-blindness without agraphia. On the other hand, it is equally clear that even at the end, when the pathological lesions had attained their maximum development, the softening had not extended into the occipital lobe. We seem, therefore, driven to the conclusion that the word-blindness must have been due to the softening of the angular and the supra-marginal gyri.

What I take to be another example probably belonging to this group is to be found in a patient under the care of Charcot, whose case has been recorded in great detail by Bernard.[13] It is an extremely interesting case, and here, as in that of Sérieux, previously quoted, the destruction of the visual word-centre does not seem to have been complete, as the patient could still recognise individual letters. The following are some of the principal details.

CASE 36.—A man, aged thirty-five years, after unusual excitement, was suddenly seized with right hemiplegia and loss of consciousness. The next day, on recovering consciousness, he stammered and substituted one word for another. At the end of three weeks the disturbance in speech had almost entirely disappeared; the hemiplegia had been gradually subsiding, so that he could now hold a pen and write very legibly. About this time, wishing to give some order about his business affairs, he took a pen and wrote what he wished to have done; then, thinking he had forgotten something, he asked to see the letter that he had just written, but found he was unable to read it. He had been able to write, but could not read what he had written just before. He was also unable to read printed matter. He was seen five months after the onset of his illness by Charcot, who ascertained that there was no longer any hemiplegia or aphasia of motor type, but that in addition to the alexia there was a forgetfulness of a certain number of nouns and proper names. It was observed that he could write a long letter without any notable mistakes in orthography. "I write," he said, "as if I had my eyes shut; I do not read what I write." In fact he wrote quite as well with his eyes closed. Having written his own name he was asked to read it. "I know very well," said he, "that it is my name that I have written, but I can no longer read it." Nevertheless, when it was insisted upon that he should read some written words, it was observed while he was making efforts to do so that with the tip of his right index finger he traced one by one the letters that constituted the word, and he was thus able with much trouble to say what the word was. Or else when he was striving to read he traced in the air with his finger the letters placed before him. It was found that he had much more difficulty in reading print after this fashion than ordinary writing, apparently because of his lack of practice in tracing the former kind of characters. Again, if when his eyes were closed a pen were put into his hand and the latter guided so as to make it write certain words, he was able to say immediately and without hesitation what those words were. He knew separately all the letters of the alphabet, except q, r, s, t, and especially x, y, z. Though he could not make out these latter letters when they were isolated, he nevertheless wrote them easily when they formed part of a word. Numerals he recognised well, and was able easily to perform certain simple operations; but when the multiplications were a little complex he made mistakes. This patient suffered also from right lateral hemianopsia.

In the absence of a necropsy it cannot be definitely said that this case belongs to the group now under consideration rather than to that which is next to be considered. Looking to the fact, however, that a hemiplegic condition existed at first, that there was no hemianæsthesia or hemiachromatopsia, and to the very limited nature of the clinical defects subsequently remaining, it seems to me distinctly less probable that the patient's condition was due to lesion in the occipital region than to one further forward which also involved the visual word-centre itself. If that were the case, the reading by means of kinæsthetic impressions would mean that the excitations of that centre produced by the finger tracing successively the outlines of letters must have been conveyed backwards along the commissure *f' f''* (Fig. 5) to the auditory word-centre, there arousing the corresponding auditory word memories, and subsequently passing over to Broca's centre preliminary to articulation of the words.

It will be observed that in each of these three cases, in which word-blindness has been present without agraphia the patients have been more or less educated persons well



[12] American Journal of Medical Science, March, 1891, p. 219.

[13] De l'Aphasie, 1885, pp. 77-90.

Hosted by Google

accustomed to write, and that in the first two, at all events, the incitations could not have come during their illness from the damaged visual word-centre. Therefore it seems only open to us to suppose that these patients were able to write spontaneously or from dictation simply because they were able to call up the familiar activity of the cheiro-kinæsthetic centre directly at the instigation of the auditory word-centre. It is well known that many voluntary movements during the

FIG. 5.

period that they are being acquired, and sometimes for long afterwards, require for their execution the active coöperation of the visual centre, though at a later period the guidance of the kinæsthetic centres may suffice for their production.

(6) DEFECTS RESULTING FROM ISOLATION OF THE LEFT VISUAL WORD-CENTRE.

Isolation of the visual word-centre is a term employed here in the same sense that isolation of the auditory word-centre was previously spoken of—it is not a complete isolation, but merely a cutting of the centre off from all its own afferent fibres, as well as from all communication with the corresponding centre of the opposite hemisphere. The clinical condition itself was first referred to by Wernicke[14] as a companion to the state described by Lichtheim as subcortical sensory aphasia or isolated speech deafness. Wernicke named this condition "subcortical alexia," while it has since been re-christened by Déjerine (who is followed by Mirallié) as "pure word-blindness." The question as to which nomenclature is to be adopted is therefore a little embarrassing. Seeing, however, that, as I have shown, each of these clinical groups of symptoms may be produced in a double way—that is, either by cortical or by subcortical lesions—it seems clear that the term "subcortical" as applied to these conditions by Lichtheim and by Wernicke would, if preserved, lead to great confusion. It seems best, therefore, to adhere to Déjerine's nomenclature and speak of "pure word-deafness" and "pure word-blindness" respectively, but with the understanding that these defects are not necessarily due to subcortical lesions.

The cases of pure word-blindness with which we are now concerned, in which the visual word-centre remains intact, are comparatively few in number. Three complete cases have been recorded with necropsies, whilst of two others the clinical details only have been published. Although the two latter cases probably belong to this type, there is, of course, the possibility that they may rather belong to the second group of cases included in the last section. I shall first give some brief account of the three complete cases, and subsequently discuss the mode in which the lesions found may be considered to be capable of giving rise to so remarkable an assemblage of symptoms.

The first of these cases to be recorded which was followed by a necropsy is one of great value; it was most carefully observed, and has been published in very full detail by Déjerine.[15] The following is the abstract that he gives by way of preface to the fuller details, which will, however, well repay a careful study.

CASE 37.—This patient was a man, aged sixty-eight years, of more than ordinary intelligence and culture. Word-blindness was complete, both verbal and literal. Musical blindness was also complete. There was preservation of ability to read figures and also to calculate. There was no trace of word-deafness, no trace of disturbance in articulate speech, and internal language was preserved. There was no object-blindness or optic aphasia; mimicry was perfect and very expressive; there was perfect preservation of spontaneous writing and of writing from dictation—the patient could thus write whole pages correctly. Writing from a copy was very difficult and defective. There was partial right lateral hemianopsia with complete hemiachromatopsia. There was integrity of motility, and of sensibility general and special, as well as of the muscular sense. The same symptoms persisted for four years. Sudden death occurred after the patient had presented for ten days total agraphia with paraphasia, without any trace of word-deafness. There had been perfect preservation of mimicry and of intelligence. At the necropsy recent lesions were found in the left hemisphere in the form of red softening in the inferior parietal lobule and in the angular gyrus. There were old lesions (*plaques jaunes*) situated in the lingual and the fusiform lobules, in the cuneus, in the white substance of the occipital lobe, and in the posterior extremity of the corpus callosum. The optic radiations were markedly atrophied. The right hemisphere was intact.

The notable features of this case are the absence of any hemiplegia; the combination of complete right lateral hemiachromatopsia with partial right hemianopsia; the absence of word-deafness or speech defect of any kind; the absolute word-blindness coupled with ability to write freely both spontaneously and from dictation, whilst ability to copy writing was very defective; and the length of time that these symptoms lasted without change. The subsequent sudden supervention of complete agraphia associated with paraphasic speech, followed by the discovery of a recent lesion in the angular gyrus and adjacent parts, were also very significant features of the case. Comments upon the old lesions found had better be reserved till some account has been given of the other two cases.

These cond case was recorded by Wyllie[16] two years later, some of the principal details being as follows.

CASE 38.—A man, aged seventy-two years, formerly a clerk of the works, but then a collector of accounts for mercantile men, came as an out-patient to the Royal Infirmary of Edinburgh on Dec. 12th, 1889. About six weeks previously, when in the street, he had a very severe attack of vertigo, and ten days later a feeling of coldness and heaviness throughout the right half of the body. At this time also he discovered that he was word-blind. He could not read even his own name. At first he was even letter-blind, but before coming to the infirmary he had recovered sufficiently to be able to recognise individual letters, though he could read no single word without spelling it. On examination no right hemianæsthesia was found, but typical right hemianopsia, with marked contraction of the remaining left halves of the fields of vision. The contraction was so marked that he saw things as if looking at them through a tube. There was no agraphia; he could write well and made very few mistakes in spelling, such as he did make being evidently due not to his cerebral condition but to defective education. Although he expressed himself in writing with ease and fluency, he could read the writing only word for word, after spelling each word letter by letter. As to spoken speech, the patient expressed himself with great liveliness and volubility, being never at a loss for a word except in the case of proper names, which he was apt to forget. There was no forgetfulness of the names of things and no paraphasia. His intelligence seemed very good, but he complained of a sense of confusion in his head. This, together with his word-blindness, had made him quite unable to continue his occupation of collecting accounts. He died four years later (Jan. 23rd, 1893) of hepatic disease, with jaundice, and at the necropsy the following lesions were found: In the left hemisphere there was atrophy of the inferior surface of the occipital lobe, with a shrivelled condition of the whole lobe. Subsequent examination of sections showed softening of the white substance forming the floor of the posterior cornu of the lateral ventricle, the cornu itself being extremely dilated. The grey matter of the occipital convolutions was not involved in the softening, but the white substance was atrophied from the tip of the occipital lobe as far forwards as the cerebral peduncles. The convolutions affected were the lingual and the fusiform lobules, together with the posterior third of the gyrus hippocampus. The angular gyrus and Broca's convolution were intact.

The third case was reported in the same year by Redlich,[17] of which the following is an abstract.

CASE 39.—A man, aged sixty-five years, a copyist, had some slight cerebral symptoms for one month only in 1891. A year later he had an apoplectic attack, and on examination two days afterwards his intelligence was found to be slightly enfeebled and right lateral hemianopsia was detected. There was also slight paresis of the right arm and the right side of the face, together with slight diminution of sensibility throughout the right side of the body. There was no word-deafness, and spontaneous speech was unaffected. He had difficulty in naming objects shown to him. He could recognise the number of syllables in words. He sang perfectly both the words and the airs of popular songs. There was complete word-blindness, literal and verbal, both for print and manuscript. He could read numerals slightly. He could only write the first syllable of his name, and could not copy at all. At a second examination, one month later, the following facts were noted. Spontaneous speech was perfect, except that he confused certain words, and had sometimes a little difficulty in finding the right word. The word-blindness was still complete. He then wrote his name very correctly; he also wrote a great number of words slowly and with difficulty, both spontaneously and from dictation, sometimes forgetting a letter. The writing was tremulous, but correct. He copied with difficulty, letter by letter. Death occurred one year and a half after the date of this attack, and at the necropsy the following were the lesions in the left hemisphere: A focus of softening was found involving a great part of the calcarine fissure and the lingual and fusiform lobules, and extending to the posterior part of the occipito-parietal fissure; the cornu ammonis was atrophied;

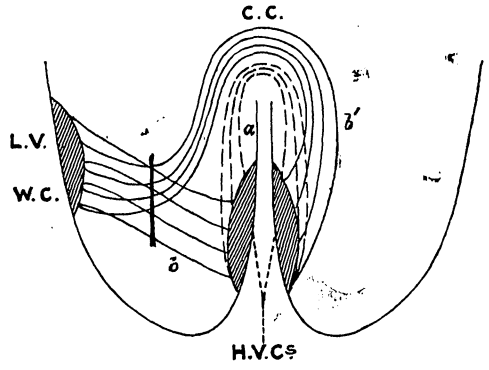
the cortical softening invaded the white substance of the occipital lobe and of the fusiform lobule, as well as the posterior part of the thalamus, the tail of the caudate nucleus, and the median portion of the corona radiata. Sections in series of the occipital lobe were made and examined microscopically, with the following results. At the tip of the lobe both the white and the grey substance were intact. The focus of softening corresponded with the fusiform lobule, and the inferior half of the lingual lobule. The forceps major was degenerated only in its median portion; its supero-external portion being intact. The tapetum was in part preserved. The inferior longitudinal convolution as well as the optic radiations were degenerated. The hippocampal gyrus was much altered, as well as a part of the third temporal.[18]



It will be observed that in each of these two cases, as in that of Déjerine, there was no motor paralysis, and only a very slight amount of right-sided hemianæsthesia. There was right hemianopsia in each, but no mention is made of hemiachromatopsia in the cases of Wyllie and Redlich, or of the ability to read words by means of kinæsthetic impressions, though both were present in the case of Déjerine.[19] It seems highly probable, however, that one if not both of these characteristics might have been met with had they been specially looked for. They both existed in one of the two incomplete cases before referred to—namely, in one observed by Gaucher, and recorded by Mirallié[20]; while in the second of these cases, recorded by Batterham,[21] though there is no mention of hemiachromatopsia, the ability to read words by aid of kinæsthetic impressions was present. Word-blindness was not complete in this case, and Batterbam says: "When asked to spell out a word written in the 'round hand' of the copy books, she failed with several letters; but on being told to copy the unrecognised signs, or to run her pencil over them as if writing them, she in most cases recognised their name and significance. This experiment was repeated several times, and the patient was delighted to find that she could 'jog her memory' of letters in this way." Both these cases are well reported, and are worthy of careful study, although there is no record as to the pathological causes of the clinical condition.

The lesions found in each of the three cases where a necropsy was made have shown a striking similarity. In each there was softening and atrophy of the white substance of the occipital lobe, together with more or less damage to certain convolutions—that is, to the lingual and fusiform lobules as well as the hippocampal gyrus and the cuneus, or, speaking more generally, to some of the convolutions on the under and inner surface of the occipital lobe. It seems quite probable, however, that the lesions of the convolutions may be of little significance so long as there is the presence of extensive destruction of the white substance of the occipital lobe. Nothing more definite can be said on this subject at present. Déjerine attaches most importance to the destruction of portions of the white matter—namely, of that in which would be included the "optic radiations" of Gratiolet, the fibres proceeding from the left half-vision centre to the left visual word-centre, as well as the fibres from the right half-vision centre to this same word-centre. This he indicates in a diagrammatic figure of some complexity.

It is clear from the explanation that Déjerine advances of Case 37,[22] and also from what he says elsewhere, that he does not believe in the existence of auditory and visual word-centres in the right hemisphere in ordinary right-handed persons. On this subject he takes much the same view as Lichtheim, and now explains "pure word-blindness" in a fashion analogous to that by which the latter explained "pure word deafness"—namely, by supposing the severance from the left visual word-centre of the associational fibres connecting it with the general visual centre in each hemisphere (see Fig. 6).

I, however, believe in the existence of a visual word-centre in each hemisphere (though unequally developed), and that the two are brought into functional relation with one another by means of commissural fibres in the posterior part of the corpus callosum. I believe also that each of these visual word-centres would be in relation by other associational fibres with the half-vision centre of its own side (which both of us suppose to be commissurally connected with its fellow); and that Déjerine's form of pure word-blindness may be produced by severance of the associational fibres between the left visual word-centre and its corresponding half-vision centre, together with a lesion of the commissure between the

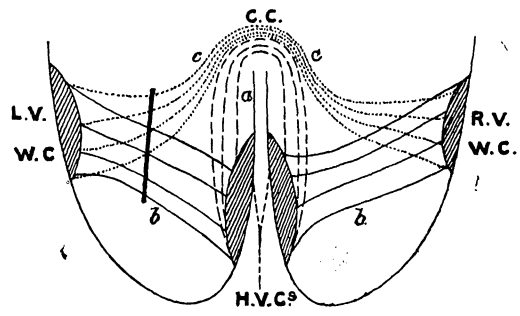


FIG. 6.

A simplified diagram representing Déjerine's view as to the mode of production of pure word-blindness. H. V. C., Half-vision centres. L. V. W. C., Left visual word-centre. C. C., Posterior extremity of corpus callosum, containing commisural fibres *(a)* connecting the half-vision centres, and also fibres *(b)* from the right half-vision centre to the left visual word-centre. (The "optic radiations" have been omitted.) The dark line indicates the site of a lesion which would cut off the left visual word-centre from the half-vision centre of each side.

two visual word-centres, in some part of its course. The isolation of the left visual word-centre would thus be complete; and brought about, moreover, in the same sort of way that I have postulated for the isolation of the auditory word-centre in the condition that Déjerine calls "pure word-deafness."

FIG. 7.

A diagram representing my view as to the mode of production of pure word-blindness. C. C., Posterior extremity of corpus callosum. *c*, *c*, Commissural fibres connecting the two visual word-centres. *b*, *b*, Fibres connecting each half-vision centre with the visual word-centre of the same side.

The commissure between the two word-centres may be damaged, in accordance with my interpretation, by the lesion in the white substance of the occipital lobe extending far enough forwards to involve them, just as Déjerine supposes those from the right half-vision centre to have been destroyed; or else by a separate lesion in the posterior part of the corpus callosum, such as was actually found in Déjerine's case, or in the part of it known as the tapetum.[23]

When we consider how one eye suffices for perfect vision, although only one-half of the proper amount of visual fibres goes to each half-vision centre, we may see all the more fully how complete and intimate must be the co-activity of these centres in vision, even when one eye only exists. That being so, it would be in vain with our present imperfect knowledge to attempt to define the actual mode of association of the half-vision centres with their outlying portions which we name

[18] Concerning some of the less familiar, though for us very important, structures mentioned above it may be well to refresh the reader's memory by quoting what Schäfer says in Quain's "Anatomy" (tenth edition, 1893, p. 129), when speaking of the posterior extremity of the corpus callosum. "The fibres," he says, "from the body and upper part of the splenium which curve over the lateral ventricle form the *tapetum*, whilst a large mass of fibres from the splenium proper curves round into each occipital lobe and is know as the *forceps major*."

[19] Déjerine is inclined to think that achromatopsia may be produced by lesions in the lingual and fusiform lobules. If the hemianopsia were complete, however, from destruction of the "optic radiations," there could be no achromatopsia.

[20] Loc. cit., p. 191.

[21] Brain, 1888, p. 488.

[22] Loc. cit., pp. 87-89.

[23] The tapetum may perhaps include the commissural fibres between the two visual word-centres, and it is specially stated in Redlich's case that these fibres were in part degenerated, as also was the forceps major, which probably includes the fibres connecting the two half-vision centres with one another.

Hosted by Google

visual word-centres. All I can say is that such an arrangement as I have previously indicated seems to me to be much more in accordance with all known probabilities than that of Déjerine, who assumes that the right angular gyrus has practically no visual functions,[24] just as he assumes that the posterior half of the right upper temporal convolution has no auditory functions. What I have said towards the end of the last section but one of the first lecture, as well as what we know as to the modes in which recovery takes place in various forms of speech defect, may be considered to lend support to my view.

As I have already indicated, the two modes of producing pure word-blindness are pretty strictly comparable, *cæteris paribus*, with two modes of production of pure word-deafness. One of these forms, which for the sake of distinction may be termed the parietal type of pure word-blindness, is brought about by destruction of the left visual word-centre in persons by whom writing can be executed under the instigation and guidance of the left auditory word-centre, while the other (Déjerine's form), which might be called the occipital type, is due to isolation of the left visual word-centre from the half-vision centre of its own side as well as from the opposite visual word-centre.

At present there seems no very definite means of diagnosing these two types of pure word-blindness from one another during life. The following considerations may, however, afford some help:—

Parietal Type of Pure Word-blindness.	*Occipital Type of Pure Word-blindness.*
Possibly some right-sided paresis.	Probably no right-sided paresis, but possibly some slight right hemianæsthesia.
Speech often slightly paraphasic.	Speech not affected, or slightly amnesic only.
May be no hemianopsia or hemiachromatopsia.	Hemianopsia always, and when incomplete probably also hemiachromatopsia.

These seem to me to be the only approximations to differential characteristics that can be suggested at present, some of them being based upon the fact that destruction of the visual word-centre may be associated with a lesion in the parietal region, and consequently may be associated with some amount of right-sided hemiparesis; while in the cases of occipital type, if the lesion of the occipital lobe extends sufficiently far forwards, we may get more or less marked hemianæsthesia without any motor paralysis. The association of alexia without agraphia in a person whose speech is not appreciably interfered with, and who has slight hemianæsthesia without paralysis, would, in fact, afford strong presumptive evidence that the pure word-blindness was of the occipital type.

(7) Defects Resulting from Combined Lesions in the Left Auditory and Visual Word-centres.

It will have been seen from the cases already recorded that destruction of the left auditory word-centre or of the left visual word-centre alone, and especially in the last case, may be quite compatible with the preservation of a fair amount of intelligence. The result is, however, altogether different when both these centres are badly damaged at the same time. The unfortunate individuals thus affected are generally reduced to a most deplorable condition, seeing that they can usually neither speak nor write intelligibly, and that they are unable to understand the speech which they hear or the language they may see either in writing or in print. They can mostly communicate with others, and be communicated with, only by means of signs and gestures; and at the same time they must necessarily suffer a very distinct amount of mental impairment, owing to the blotting out of the principal linguistic symbols by means of which all but their most elementary thinking processes are carried on.

Although this is the kind of condition that has been met with in the great majority of these cases, yet a careful examination of their published records shows that, as in cases where there is destruction of the left auditory word-centre, so here with combined lesions of the auditory and the visual word-centres, a considerable variation is met with in different cases. These variations depend partly upon differences in the relative completeness of the lesion in one or other of these centres; and in cases where one of the centres is incompletely destroyed probably also to a considerable extent upon individual variations in original endowment—that is, upon the question whether the patients are "auditives" or "visuals," as well as in part upon their degree of education. Where the destruction of both the left word-centres has been complete, moreover, variations in symptoms may depend upon the degree of development of the corresponding centres in the opposite hemisphere.

Taking the lists given by Amidon and Mirallié, and including one case by West[25] not contained therein and two of my own, I find seventeen cases in all of this double lesion; of these, it seems desirable to exclude two—one by Chauffard, as the patient only lived three days, and one by Shaw, seeing that the patient was demented and that the clinical record is very incomplete.[26] Of the remaining fifteen cases, in three the lesion was complete in the visual and partial in the auditory word-centre (in Amidon's No. 4, Mirallié's No. 38, and in West's case); in two it was complete in the auditory and partial in the visual word-centres (in Amidon's Nos. 1 and 2); in four cases it was incomplete in both word-centres (Mirallié's Nos. 8, 23, 24, and 48); whilst in six cases the lesion was pretty complete and equal in both word-centres (Mirallié's Nos. 5, 16, 26, and 29, and my own two cases).

Looked at from another point of view—that is, as to the kind of speech defect presented by these fifteen cases—I find that speech was more or less good in two (Amidon's Nos. 1 and 2); that there was more or less marked paraphasia or actual jargon speech in seven (Amidon's Nos. 5. 16, 23, 29, 38, and 48. and West's case); and more or less complete speechlessness in six (Amidon's No. 4, Mirallié's Nos. 8, 24, and 26, and my own two cases). These very different results may at first seem very astonishing to others, as they did to me. But the more one thinks of cases presenting this double lesion, in which speech was only slightly paraphasic or fairly good, the more it seems necessary to suppose that the auditory word-centre of the right hemisphere must have been able to act upon and with the left glosso-kinæsthetic centre. These cases cannot be explained by supposing that speech was produced by the right auditory word-centre acting with the right glosso-kinæsthetic centre, because all present knowledge goes to show that this could only be brought about after a long interval, during which these centres were educated to act together. In the cases in question, on the other hand, there was evidently no such interval, seeing that the modified speech was initiated in each case just after the brain lesion occurred. It is worthy of note also that in the two cases in which speech was best preserved (Amidon's Nos. 1 and 2) the visual word-centre was only partially damaged, so that some help may also have come from its coöperation.

A few cases may now be given in illustration of the different degrees of speech defect associated with this double lesion with which we are now concerned. The first is one that was published nearly twenty years ago by Broadbent in which there was well-marked jargon-speech.[27] It is given here only in abstract, and is No. 5 of Mirallié's list.

CASE 40.—A man, aged sixty years, previously very intelligent and able to read and write well, but of intemperate habits, had had some sort of fit two weeks before admission to St. Mary's Hospital. From that time he had kept his bed and had been unable to speak intelligibly. When seen there was no hemiplegia, but slight paresis of the right side of the face and some amount of right hemianæsthesia. His speech was an inarticulate jargon and preserved the same character throughout. When questions were asked he attempted to reply, but as a rule nothing resembling a word could be detected in what he said. The voice was inflected and he appeared quite unconscious that his speech was mere gibberish. He seemed to have some idea in his mind and to think that he was giving expression to it. Besides speaking after questions, he would go on talking, addressing himself to one or another of those present, the whole of what he said being an incomprehensible ramble, though at times a distinct word or phrase would slip out. When excited the phrase, "If you please," was several times heard distinctly. He seemed to understand nothing that was said to him, and when told to shut his eyes or give his hand there was never any attempt at compliance. He was similarly quite unable to read writing. [Nothing is said about his ability to read print or his capability of writing, but he was probably incapable of doing either.] He would sit up in bed and appear to watch with interest what was going on in the ward. When the meals were brought in he looked for his portion, and ate his food

[24] One result of this supposition is that in endeavouring to account for the writing of an aphasic person with the left hand he assumes that the right hand and arm centres are stimulated from the one and only visual word-centre, the left—in fact that the left hand and arm are in part under the direction of the left hemisphere for writing movements, while for all other kinds of movements of the left hand and arm the right visual word-centre would, as usual, coöperate with the kinæsthetic centres of the same side. I must confess that this does not seem to me to be very probable.

naturally. When the bowels were about to act he called the attention of the nurse by knocking on his locker and then pointing to the commode. There was never anything extraordinary in his behaviour. He died about three weeks after his admission to the hospital. At the necropsy softening of the posterior part of the left hemisphere was found in the region supplied by the third and fourth branches of the Sylvian artery. The convolutions softened were the supra-marginal lobule and the angular gyrus throughout their whole extent, and also the posterior half of the first temporo-sphenoidal gyrus, together with some portions of adjacent occipital and posterior parietal convolutions. Broca's region and the anterior half of the brain as a whole were unaffected.

This is a fairly typical case, the destruction of both the word-centres being complete and speech reduced to an unintelligible jargon. In the next case (No. 29 of Mirallié's list) the lesion was equally complete, though the derangement of speech was less marked—a very bad form of paraphasia being present rather than jargon-aphasia. It has been described at length by Déjerine,[28] but I give it here only in abstract.

CASE 41.—A man, aged sixty-three years, was admitted to the Bicêtre on July 3rd, 1890, having had an apoplectic seizure on the previous evening. The patient was of vigorous appearance and intelligent face, and was said to have been able to read and write previously to his illness. When examined on July 4th he was found to be in a semi-comatose condition, from which he could only be roused momentarily with difficulty. He remained in this condition for four days, and then gradually recovered consciousness. On July 20th he walked about the ward and showed no appreciable hemiplegia. He began to speak two or three days before, but his speech was much altered and he understood nothing of what was said to him. On saying to him, "Comment vous appelez-vous?" he replied, "Je suis et, surtout c'est-à-dire, c'est-à-dire, non, je ne peux pas po pa." "Quel métier faisiez-vous?" "Mon père se nommait, non, peux pas." The only words that he pronounced in a suitable manner were "bonjour" when one approached his bed, and "merci" when one gave him something to eat or drink. When a newspaper or some manuscript was shown to him he looked at the paper and then at the person who had given it to him, and it was evident that they had no meaning for him. When a pen was given him he held it correctly as if he were going to write, but made only meaningless marks on the paper, either when he was left to himself or when a phrase was dictated to him in a loud voice. If one gave him a phrase in manuscript to copy he copied the letters one after the other, but very badly and the words were illegible. Nevertheless, the general form of the letters was preserved, while in his spontaneous writing or that from dictation he was incapable of tracing even the rough outline of a letter. The patient recognised, however, quite well all the objects and persons around him. His hearing was also intact, and the slightest sound behind him would cause him to turn his head. On Dec. 4th, 1890, the word-deafness remained about the same, but he could now recognise one question, "Comment vous appelez-vous?" and gave his surname correctly. But to any question that anyone put to him immediately afterwards he still answered by giving his name. If after an interval one came back to him again he no longer replied as before with his name to all questions, but by words or phrases that had no relation to the question. For example: "D.: Qu'ayez-vous fait hier? R.: Mon père était marchand de vins.—D.: Dans quel hôpital êtes-vous? R.: Je ... vou .:. je voudrai ... non ... papapa ... tou.—D.: Quel age avez-vous? R.: J'avais cent soixante-trois.—D.: Quel métier faisiez-vous? R.: Trois ans, six ans, trente trois, jamais trente un ans jamais, trente, trente, trente, trente-trois ans, jamais trente, trente, trente-trois ans." The patient was still unable to read, but for the last few days he had recognised his name and been able to pronounce it aloud, though he could do this with no other word. Right lateral hemianopsia seemed to be present. The agraphia remained complete as before. The patient remained in about the same condition for another three weeks; then his whole condition changed, he gradually sank into a semi-comatose state (owing to the establishment of a large area of softening in the right hemisphere), and about a month later he died. At the necropsy, in addition to a large area of recent softening in the right hemisphere, there was found a large area of yellow softening completely destroying the visual and the auditory word-centres of the left hemisphere, which also extended forwards into the parietal region and backwards into the occipital. Section of the hemisphere also showed that the lesion extended inwards through the white substance as far as the posterior cornu of the lateral ventricle.

It is worthy of note that there was here no speech at all for sixteen days from the onset of the seizure and for about eight days after the recovery of consciousness; and, looking to the completeness of the destruction of the left auditory and visual word-centres, it is difficult to suppose that the speech which was subsequently possible could have been effected without the aid of the right auditory word-centre. Much the same thing may be said in reference to the next case, although the speech trouble was more like that met with in incomplete motor aphasia. It is No. 8 of Mirallié's list, and has been recorded by d'Heilly and Chantemesse.[29] The following is a brief abstract.

CASE 42.—A woman, aged twenty-four years, became suddenly speechless on Oct. 12th, 1881. She entered a hospital at once. To all questions put to her she would repeat five or six times with different intonations. "Because, because, because." Sensibility and motility seemed perfectly intact. On Oct. 15th, in reply to a question, she answered, "Thank you, sir, I am better"; though, as Bernard points out, she was never able to repeat it. She looked very intently at the speaker, but words seemed to wake in her no image, no remembrance. When told to put her hand to her head she hesitated an instant and appeared to be trying to remember something, but she remained motionless. When the command was accompanied by a suggestive gesture she quickly obeyed. Hearing and vision were both preserved. Her power of calculation seemed preserved, as she could play écarté skilfully, making no errors as to colour or value. When asked, she called her knife, tumbler, food, wine, and plate each "du plan." When an orange was held out to her she answered all questions, "Yes, sir," and reached for the orange. Once when her soles were tickled she said, "Please don't, sir." She could neither copy, write from dictation, nor read. She died on Nov. 3rd from marasmus. There was found at the necropsy a softening from thrombosis of the fourth branch of the left Sylvian artery. This softening involved the upper posterior half of the first temporal convolution, most of the inferior parietal lobule, the supra-marginal gyrus, and some of the sigmoid gyrus. The softening affected only the cortex, and on section was seen to implicate only the extreme posterior hidden part of the insula.

It seems clear from the records of the necropsy that the left auditory word-centre was here only partially destroyed, so that perhaps we need not suppose that help came from the right auditory word-centre for the production of the few short sentences that this patient was capable of uttering.

In a patient recently under my own care, suffering from a softening of the same region of the brain, during the three weeks that elapsed before death occurred there was absolutely no speech. The following are a few notes concerning this case.

CASE 43.—A woman, aged fifty three years, was admitted to University College Hospital on April 28th, 1896. Whilst suffering from inflamed varicose veins in the left leg she began to feel ill on April 22nd, suffering from headache and irritability. On the morning of April 26th these thrombosed veins were rubbed with an embrocation. She went to bed on the night of the 26th with no change in her symptoms, but the next morning she fell from the bed in an unconscious condition. She twitched her left arm and muttered indistinctly for a time, and remained in a stuporous state up to the time of admission (9 A.M. on the 28th). She was found to be semi-conscious and paralysed on the right side, showing some irritability on examination, throwing her left arm and leg about, and occasionally uttering some inarticulate sounds. There was no cardiac bruit; the respirations were natural. Her temperature was 100·8° F. She remained in much the same condition, semi-conscious, yawning frequently, rather restless at times, till May 5th, when she became more conscious, but made no attempt to speak or even utter any sound. She could not be induced to protrude her tongue. She did not attempt to respond or show that she understood any simple request, and appeared to be perfectly word-deaf. She took no notice of written sentences held before her. The right arm was rather rigid. On May 11th she seemed more conscious than she had been but did not speak, nor did she seem to understand anything. One-fourth of albumin was found in the urine. On May 14th she began to suffer from sickness and some diarrhœa (the albumin in the urine persisting), together with lung complications, and she died about midnight on May 18th. At the necropsy the third frontal and the lower part of the ascending frontal convolution were found to be healthy, both externally and on section; but the lower part of the ascending parietal, together with the whole of the supra-marginal and angular gyri and the two upper temporal convolutions, were completely softened throughout. The softening extended to, and partly involved, the outer part of the thalamus and the corpus striatum; it also extended backwards slightly into the occipital lobe. The right hemisphere showed no focal lesion of any kind.

Here, then, there was complete loss of speech as a result of destruction of the auditory and the visual word-centres in the left hemisphere, together with some adjacent tracts of brain tissue, which lasted continuously for just over three weeks. We have seen that Déjerine's patient (Case 41) also remained speechless for sixteen days after the onset of his seizure, and then began to talk in a badly paraphasic fashion. It seem probable, therefore, that my patient might also have developed some sort of power of speaking had she lived longer.

My second case belonging to this group is one of a very extraordinary nature in many respects, the patient having lived over eighteen years after his seizure, and his speech defects having remained constant throughout almost the whole of this period. His spontaneous speech was limited to a few words, and, though he was neither word-deaf nor word-blind, both the auditory and the visual word-centres of the left hemisphere were completely destroyed. The record of this remarkable case, together with illustrations of the brain, will be published in the forthcoming volume of the Transactions of the Royal Medical and Chirurgical Society for 1897.

Time does not permit of my referring either to "object-blindness" or so-called "optic aphasia"—interesting conditions, one or other of which may sometimes be met with in association with such cases as we have just been considering, where lesions producing speech defects extend into the occipital lobes. These conditions, together with other parts of the subject, I shall hope to deal with before long in some other way.

My object in these lectures—after laying down some general principles needful, as I consider, for the proper understanding of speech defects, and culminating in my non-recognition of any distinct and separate "centre for concepts," such as

[28] Comptes Rendus de la Société de Biologie, 1891, p. 167.

many postulate—has been to limit myself to a definite set of problems concerning the functional relations of the four cortical word-centres. I have striven to show that the overweening importance attached by many to the functions of Broca's centre is not justified by facts—that too many disabilities have been supposed to result from its destruction by some, and that the power of independent activity ascribed to it by others does not exist. I have tried to show the way in which these views have influenced others to deny the existence of a cheiro-kinæsthetic centre and the fallacious nature of many of the arguments on which they rely. Again, while alluding to the unsatisfactory nature of the nomenclature at present in vogue, I have tried to show that the so-called "sensory aphasia" of Wernicke has no claim, as he supposed, to an independent existence, but really includes a large number of distinct conditions, each of which has to be studied separately and in detail. The great importance of the auditory word-centre has been dwelt upon, as well as the variety of defects produced by functional and structural derangements of this region, and also by its isolation. A study of these results, taken in conjunction with that of the less varied defects resulting from disease and from isolation of the visual word-centre, led to some novel conclusions. We have seen the enforcement of the view to which we had previously been driven as to the comparative powerlessness of Broca's centre alone; we have found evidence for the existence of an unexpected possible amount of functional substitution between the visual and the auditory word-centres for the production of speech and writing respectively; and, still more surprising, we have found reason for believing that both auditory word-centres are accustomed to act upon Broca's region for the production of speech—as well as much evidence tending to favour the view that even in comparatively simple perceptional and intellectual operations very extensive cortical areas in both hemispheres of the brain are called into simultaneous activity.

I can only say, in conclusion, that my best thanks are due and are given to the College for the opportunity that has been afforded me of submitting the results of my labours to its consideration, and to you all for the patient manner in which you have listened to minute details which, I fear, must have been often wearisome and somewhat difficult to follow.

THE MALIGNANT TUMOURS OF INFANCY, CHILDHOOD, AND YOUTH.

BY W. ROGER WILLIAMS, F.R.C.S. ENG.,
FORMERLY SURGEON TO THE WESTERN GENERAL DISPENSARY; AND SURGICAL REGISTRAR, MIDDLESEX HOSPITAL.

DURING the last half century vast additions have been made to our knowledge of the malignant neoplasms of early life. Unfortunately, most of these precious acquisitions are still buried in the archives of learned societies, where they are beyond the ken of practitioners. In this country not a single endeavour has hitherto been made to make known to the profession the general results thus attained; and in the standard text-books—even in those that deal specially with the diseases of children—little or nothing is to be found on the subject. Hence these diseases are frequently overlooked, and the real nature of the malady is often never even suspected. I was particularly struck with this deficiency; when, desiring to compare my own experience of this particular class of tumours with that of others, I found to my surprise, that no standard of comparison existed, for my predecessors had recorded nothing but isolated cases and small groups of such cases. Under these circumstances I determined to supply the deficiency by collecting cases and reviewing the chief publications in the light of my own experience. Of this undertaking the present article is the outcome. The subject having proved much larger than I at first anticipated, I have endeavoured to make my review representative rather than exhaustive.

Notwithstanding the large number of instances of malignant disease in early life lately recorded, it will be gathered from the subjoined data that fewer cases originate during infancy and childhood than at any other periods of life. Of 941 consecutive malignant neoplasms under my own observation only 25—i.e., 2·6 per cent.—commenced under the age of twenty years; of these, 8 started in the first quinquenniad, 2 in the second, 6 in the third, and 8 in the fourth. This subject is further illustrated by the following table from the Registrar-General's Report for 1886, which shows a lower proportion of cases at early periods—viz., 1·15 per cent. under twenty years of age:—

TABLE I.—*Showing the Deaths due to Malignant Disease at Different Age Periods.*

Sex.	All ages	Under 1 year.	1-2	2-3	3-4	4-5	Total under 5 years.	5-10	10-15	15-20	20-25	25-35	35-45	45-55	55-65	65-75	75-85	Over 85	Total both sexes.
Males	5754	8	6	6	6	5	31	18	18	33	50	145	426	1095	1727	1555	591	65	16243
Females ...	10489	7	6	6	6	6	31	15	16	25	41	321	1313	2464	2922	2330	910	101	

It is sad to have to relate that during the last decennium the mortality due to malignant disease in early life, for the first time, showed a decided increase, although the increment of increase is proportionally much less than at subsequent age periods. This is illustrated by the following table from the Registrar-General's recently issued decennial supplement.

TABLE II.—*Showing the Number of Deaths from Malignant Disease in Early Life per Million Persons Living at each Age Period.*

Age periods.	Under 5.	5-10	10-15	15-20	20-25	All ages.
1861-70	13	7	7	7	17	384
1871-80	12	7	7	15	27	468
1881-90	20	10	11	20	35	589

It will be gathered from Table I. that the relative sex liability to malignant disease in early life shows no such marked differences as are noticeable at more advanced ages.

I have been greatly impressed, as I shall subsequently have occasion to point out, with the large proportion of the neoplasms of early life that obviously arise in connexion with embryonic developmental aberrations. This gives to the whole group a certain peculiarity, but it seems to me undesirable on this account to make a special morbid entity of these neoplasms, as Birch-Hirschfeld and others have proposed. I have found that the proportion of cases in which a history of heredity is recorded is considerably smaller than in the corresponding neoplasms of adult life, consequently I cannot corroborate Hutchinson's dictum that "malignant disease in young persons is generally inherited." The newly-born infants of mothers themselves the subjects of malignant disease are hardly ever thus affected.

Nearly all the malignant tumours of early life are of a sarcomatous nature; true cancers—i.e., malignant epithelial neoplasms—are at this period exceedingly rare.

Of my 941 neoplasms 806 were cancerous and 136 sarcomatous; in only one of the former did the disease begin under twenty years of age, whereas the latter furnished 24 cases.

With regard to the localisation of the disease, this depends largely upon the age at onset. Duzan[1] collected the records of 182 cases in early infancy, which were distributed as follows: Eye in 70 cases, kidney 45, testis 11, prostate 8, bones 5, tongue 5, brain 5, abdomen 5, lung 4, dura mater 4, pancreas 3, liver 2, tonsil 2, rectum 2, and the stomach in 1. During the third and fourth quinquenniads certain of the long bones, together with the superior

[1] For bibliography see end of article.

Hosted by Google

and inferior maxillæ, are the commonest seats of the disease.

An analysis of my 55 consecutive cases shows that 13 originated in the first quinquenniad, viz.—in the eye 7, kidney 2, testis, inferior maxilla, basis cranii, and tibia, of each 1; in the second quinquenniad 6 originated, viz.—liver, parotid, kidney, tibia, cervical lymph gland, and inferior turbinated bone, of each 1; the third quinquenniad furnished 16 cases, viz.—inferior maxilla 4, femur 3, fibula 2, tibia, humerus, acromion, parotid, thigh muscles, external ear, and retina, of each 1; in the fourth quinquenniad 20 cases arose, viz—in the femur 4, superior maxilla 3, inferior maxilla 3, lymph glands 2, testis, pharynx, kidney, parotid, basis cranii, humerus, orbit, and subcutaneous connective tissue of back, of each 1.

The great majority of the neoplasms of early life either are malignant or tend to become so; such tumours progress more rapidly, disseminate more frequently, and after removal recur with greater rapidity, than their congeners of adult life. A large proportion of these malignant neoplasms are undoubtedly congenital; that is to say, they originate during intra-uterine life. Moreover, they are often multiple *ab initio*, and not unfrequently bilateral. As I shall subsequently have occasion to mention, all tumours of this kind probably are sarcomatous; but many alleged examples of congenital "cancer" have been recorded. It must be remembered, however, that the sharp distinction now made between cancer and sarcoma is of comparatively recent origin. Many of the malignant tumours of infancy and childhood contain epithelial elements, and this has often led to their being christened "cancer." Numerous examples of this kind have been recorded, especially in connexion with the renal, testicular, ovarian, hepatic, gastric, and intestinal malignant neoplasms of early life. It is now generally recognised that the epithelial elements in such cases play only a secondary part, and that all such neoplasms really are sarcomatous.

In other instances of alleged "cancer" in early life the diagnosis has been based exclusively on the microscopical appearances, the clinical features of malignancy being conspicuous by their absence. Instances of this kind have been published in connexion with the lips, skin, external genitalia, &c. In short, I conclude that infancy and childhood are completely exempt from true cancer, using this term in the sense of malignant epithelial neoplasm. The earliest age at which cancer has been satisfactorily demonstrated is eleven years, the patient being a girl with cylinder-celled cancer of the rectum (Stern).

I have met with the following instance of rodent ulcer in a young woman in whom the disease began at the age of fourteen years.

CASE 1.—At the early age of fourteen years the patient noticed "a small pimple" of the skin of the left temple. No wart, mole, or obvious congenital blemish was previously there. In the course of a few years the "pimple" became a small, scab-covered sore. It took eight years for this sore to attain the size of a sixpence and five years more for it to attain the size of half-a-crown. It was then cauterised, after which it spread more rapidly, involving the left side of the head from the orbit to the ear. It next involved the ear and eyelids, the left sub-maxillary glands at this stage becoming slightly enlarged. Her general health remained unaffected. The ulcer was next scraped, and its peripheral parts extirpated by dissection. Rapid recurrence followed and was destroyed by Fell's paste. Two and a half years later the ulcer was much larger and more like epithelioma, with several adjacent lymph glands enlarged and hard. The disease was again freely extirpated. Three years later it was still progressing, and the orbit was invaded. No further operation was performed. The disease spread in the orbit and perforated its roof, so that the brain protruded through a large chasm. About a year later she died thus from asthenia, the total duration of the disease having been nearly twenty-two years. At the necropsy it was found that the ulceration had ravaged the whole of the left side of the head and face, from the hairy scalp to the lower border of the inferior maxilla, and from the ear to the nose. The left superior maxilla had disappeared, and the pharynx was laid open. The left orbit was eaten away, and the brain projected through its roof. There were no signs of dissemination, either in the adjacent lymph glands or elsewhere. Histologically the disease was typical "rodent ulcer."

With these introductory remarks I will now proceed to the consideration of individual cases, as they are met with in the various organs.

UTERUS.

In early life the uterus and breast are hardly ever attacked by malignant neoplasms. This immunity, which contrasts so markedly with their subsequent proclivity to these diseases, is probably due to their rudimentary condition at birth and during infancy, for it must be remembered that the essential features of their anatomy are almost entirely of post-embryonic origin. No example of congenital malignant disease of the uterus has hitherto been recorded. Under the age of twenty years uterine cancer is hardly ever met with. Of 500 consecutive cases analysed by me the earliest age at onset was twenty-two and a quarter years. Gusserow,[2] by massing the statistics of several Continental and English writers, obtained a total of 3385 cases, and of this large number only two originated under twenty years of age. The earliest age at which the outbreak of the disease has been duly substantiated is seventeen years; Schauta[3] and Glatter[4] have each recorded an instance of this kind, the cervix being the seat of the disease, which was glandular cancer. Mundé[5] has reported a case at eighteen years of age; while Beigel, Tchop, and Eckardt[6] have each met with one at nineteen years of age; the cancerous nature of the affection—"hypertrophy of the cervix with commencing cancer"—in the last case is, I think, dubious. Billroth has seen the disease at twenty years of age. Several instances of so-called cancer of the uterus at still earlier periods have been recorded; but the precise nature of these neoplasms presents some obscurity. Cases of this kind have been published by Rosenstein at two years, Laidley at two and a half years, Ganghofner at seven years, and by Barnes at nine and ten years respectively.

CASE 2.—Rosenstein's[7] patient, aged two years, came under treatment for dysuria caused by an intra-abdominal tumour, which reached far above the pubes. The inguinal glands were enlarged. She died shortly afterwards. At the necropsy a large mass of new growth was found springing from each side of the fundus uteri. There were several nodules of similar growth on the peritoneal surface of the bladder. The mucosa of the uterus, tubes, and vagina was unaffected, and the ovaries were normal. Histologically the tumour consisted of a fine, spindle-celled stroma, the meshes of which contained large polymorphic epithelioid cells. It is described by Rosenstein as "carcino-sarcoma." This anomalous neoplasm appears to me to approximate more closely to malignant anglo-sarcoma than to any other well-recognised type.

CASE 3.—In Ganghofner's case[8] a little girl, nine years old, had an eroded papillary tumour growing from the portio to the vaginal aspect of which it was attached by a distinct peduncle. The symptoms were of two years' duration. The growth was excised, but the patient died from small-pox a few days afterwards. The vagina and adjacent parts were found to be quite free from the disease, and there were no signs of dissemination either in the neighbouring lymph glands or elsewhere. Histological examination revealed the presence of hyperplastic glandular structures beneath the enlarged papillæ. They were evidently derivatives of the cervical glands, and for the most part their lumina were preserved, although the lining cells were often multilaminated. These appearances were thought to warrant the diagnosis of glandular cancer. It seems to me more like a case of non-malignant "cauliflower excrescence," of which several instances have been met with in infancy; this accords with the complete absence of dissemination, although the disease was of two years' duration. The hyperplastic glandular elements were probably of inflammatory origin.

Braetz has described an instance of endothelioma of the cervix at eighteen years of age.

Although in early life sarcomatous neoplasms of the uterus are exceedingly rare, yet they are relatively much oftener met with than cancers. Of seventy-three uterine sarcomata tabulated by Gusserow[9] four began under twenty years of age. Neoplasms of this kind generally present as polypoid tumours springing from the mucosa, and they are usually multiple. In this and in other respects they much resemble the analogous growths so often met with in the vagina of children; and both organs are occasionally thus affected, as well as the urethra and bladder. Cases of this kind have been reported by Holländer[10] in a child seven months old, by Farnsworth[11] at thirteen months, by Pick[12] at two years, by Smith[13] at three years, and by Ahlfeld[14] at three years and four months. Hereford[15] and Clay[16] have related several similar cases. Zweifel[17] has reported a case at thirteen years, and Ahlfeld[18] one at fifteen years. It is evident that these neoplasms are closely allied to the rhabdomyomatous racemose sarcomata of the portio, such as Pernice, Thiede, Rein, and others have described.

VAGINA.

The chief feature in the neoplastic pathogeny of the vagina in early life is the great relative frequency with which multiple polypoid sarcomata arise from its mucosa. In addition to their initial multiplicity these tumours present other special features; they are not unfrequently congenital, and a considerable proportion of them contain striped muscle fibres. These indications point to their origin from developmental irregularities. It will be remembered that the vagina is formed by the coalescence of two pairs of tubes at first widely separated; it is exceedingly probable that during the process of approximation and fusion fragments of muscle matrix, detached from adjacent parts, become included in the developing organ. Most of these peculiar sarcomatous tumours probably originate from dislocated cells connected with aberrant sequestrations of this kind. They have been met with at birth by Gränicher,[19] Chiari,[20] Frick, Schubert, Demme, and others. An excellent specimen of this kind is preserved in the museum of St. Bartholomew's Hospital,

Hosted by Google

which is thus described in the catalogue:[21] "A large cluster of polypoid growths removed from the walls of the vagina and from the nymphæ of a child. They were of various sizes and shapes; the largest, about three inches in diameter, was attached to the upper wall of the vagina. They were soft and whitish, some being gelatinoid and pellucid. Histological examination revealed fibro-cellular connective tissue."

CASE 4.—The history of the case was as follows:—At birth a growth "like a bunch of grapes" was observed projecting from the vagina, to the right wall of which it appeared to be attached. It was ligatured and cut off when the child was six weeks old. There was recurrence, but no further operation was done until the child was three years old, when the mass was again ligatured and cut off. This time recurrence was very rapid, for the above described growths were removed only six weeks after the second operation. It was then recognised that the whole of the disease could not be removed, especially in the vicinity of the urethra. Rapid recurrence soon set in, and the child died thus from asthenia three months later.

Growths of this kind are commonest in early infancy. Hauser[22] has met with an instance in a child six weeks old, Frick[23] at seven months, Schuchardt[24] and Kolisko[25] at one year; at rather more advanced ages cases have been reported by Körner,[26] Marsh,[27] D'Arcy Power,[28] Sänger,[29] Soltmann,[30] Pick, Münz, Ahlfeld, and others. Demme has seen a case at seven years, and Kaschewarowa-Ruduewa[31] one at fifteen years; but most cases are met with in children under five years. Growths of this kind may be limited to the vulva, as in cases reported by Thomas[32] and Volkmann. Cancer of the vagina is a very rare disease, even in advanced life, consequently it is surprising to find that of 24 cases tabulated by Kuestner[33] 2 started in young persons under twenty years. Lebert[34] and Guersant[35] have each recorded an example of epithelioma of the introitus in a child only three and a half years old, and Johannovsky[35] has reported a similar case at nine years. Probably these latter cases would be more correctly classed as sarcomata of the type described by Gow.[36]

BREAST.

In early life malignant disease of the breast is even of rarer occurrence than of the uterus. Of 1622 mammary cancers tabulated by Gross[37] the earliest age at onset was twenty-one years. Of 500 consecutive cases analysed by myself the youngest was twenty-four years of age. Haycock[38] has reported a case at twenty-one and a half years, and Erichsen[39] one at twenty-three years. Thus the first four quinquenniads are quite exempt from mammary cancer. Alleged examples of it by Lyford (at eight years), Carmichael (at twelve years), Cooper (at thirteen years), and Home (at fifteen years) were never histologically verified; we may safely assume that the disease in these cases really was sarcomatous. Of 156 cases of mammary sarcoma tabulated by Gross,[40] in 2·7 per cent. the disease supervened before the sixteenth year, the earliest being nine years old. Chambert has met with a round-celled sarcoma, the size of a fowl's egg, in the right mamma of a girl only four months old, and Vieregge with melanotic sarcoma in a young infant. A larger proportion of spindle-celled sarcomata than of other varieties arise during early life, for 12 per cent. of this variety began under sixteen years. In a small round-celled sarcomatous tumour of nine months' growth removed from the breast of a girl aged sixteen years, Billroth[41] found numerous transversely striped muscle cells. A congenital myxoma has been figured by Ashby and Wright.[42] Of 88 cases of cancer of the male breast collected by me, the earliest age at onset was twenty years; Banks[43] has seen a young man with sarcoma of the breast in whom the disease began at twenty years and four months.

OVARY.

A large proportion of the malignant neoplasms of the ovary, which are rare, occur in infants and young children. Of 12 cases in which tumours of this kind were extirpated Aldibert[44] reports that 6 were children between the ages of seven and nine years, and 1 was only four years old. These neoplasms are almost invariably sarcomatous, and both ovaries are often affected. Cases have been recorded by Brown[45] at nine months, Cameron[46] at three and a half years, Marchand[47] at four years, at six years,[48] Croom[49] at seven years, Leopold[50] at eight years, Malins[51] at nine years, Wagner[52] at ten years, Kelly[53] at twelve years, Wagner[54] at thirteen years, Smith[55] at fourteen years, and by Szabo[56] at fifteen years. Doran[57] has found papillomatous cysts in the ovary of a seven months' fœtus. Ovarian dermoid cysts have often been met with at birth, in infancy, and in childhood; but I am not aware that at such early ages malignant disease has been observed in connexion with them. Doran[58] has, however, seen an instance of this at seventeen years and Hauke[59] at fifteen years.

Several examples of alleged cancer of the ovaries in infancy and childhood have been published; but so little that is reliable is known of ovarian cancer that I hesitate to accept them as such. Mengershausen,[60] Leopold,[61] Gussenbauer[62] (at eight years), Kahlden,[63] and Hennig[64] have recorded cases of this kind. What appears to be a duly authenticated example of cancer of the ovary at fifteen years of age has been reported by Doran.[65] It is noteworthy that these ovarian neoplasms, unlike their congeners of the testis, hardly ever contain heterotopic structures such as cartilage and striped muscle—at least, I know of no recent instance in which their presence has been demonstrated.

(*To be continued.*)

THE NOTIFICATION OF TUBERCULOSIS.[1]

BY JAMES NIVEN, M.A., M.B. CANTAB.,

MEDICAL OFFICER OF HEALTH OF MANCHESTER.

THE following paper is in no sense intended to be scientific or abstruse, and I would therefore ask for some indulgence if my observations are somewhat brief and desultory.

It is requisite, however, that I should state some fundamental facts about the propagation of phthisis as a basis of action. First, then, we know more about the modes of propagation of tubercle than we do about those of any other of the infectious diseases with which we are familiar. This is sufficiently clear if we consider the facts. As a result of Koch's investigations we are aware that the tubercle bacillus is the invariable antecedent of tuberculous changes and that it is the cause of most diverse conditions, including tuberculous phthisis, tuberculous enteritis, tuberculous ulcers whether of the mouth or glands, tuberculous diseases of

[1] A paper read before the Manchester Medical Society on April 7th, 1897.

Hosted by Google

bones and joints, tabes mesenterica, tuberculous meningitis, and other conditions which I need not now enumerate. Whatever discharging lesion tuberculosis sets up the discharge contains the bacillus in greater or less abundance. It is, however, specially abundant in tuberculous sputum and in the discharges from tuberculous bowels. It is also often abundant in the milk drawn from tuberculous udders. From many experiments we are aware that if tuberculous matter is inhaled, ingested, or inoculated in animals in sufficient amount it is liable to produce the disease. We have good reason for believing that only when the discharges of tuberculous persons or animals have got dried and broken into dust are they able to produce the disease by inhalation. We have also evidence that such tuberculous dust is to be found in an active condition in the neighbourhood of phthisical persons when sufficient precautions have not been observed in the removal of infection. The tubercle bacillus is able to grow outside the body at ordinary temperatures, but only extremely slowly and under exceptionally favourable conditions. It is not probable that this factor enters largely into infection. Our chief object, then, in the prophylaxis of tuberculous diseases must be to prevent any part of the discharges from getting dried or otherwise reaching the internal organs of new persons. But it is also necessary as a subsidiary means of defence, especially in lodgings, to see that the rooms occupied by those suffering from the disease are kept thoroughly cleansed in such a manner as to prevent the dispersion of any infective matter which may have lodged and dried in them. We are further aware that the tubercle bacillus is readily destroyed by direct sunlight, and less readily by good indirect light. Inasmuch, again, as a certain concentration of infection is necessary to produce the disease, differing greatly according to the state of health of the infectee, good ventilation will clearly have the effect of diluting the infected matter and so of diminishing its capacity for mischief. Above all, thorough cleansing with water removes the bacillus, and washing with dilute solution of chlorinated lime destroys it.

No one now disputes that tuberculosis is a communicable disease or that it is communicated. The knowledge, however, is not generally a vivifying knowledge, leading to action. For this the chief reason is that the source of infection is often forgotten—often, indeed, overlooked. Take the case of a girl whom I examined as to suitability for the convalescent home in Southport. She was phthisical, and I put the usual question whether some years before she had not been a good deal with some phthisical person. She could not recollect anything, but just as she was leaving she remembered that about three years before she had nursed for several weeks a cousin who was dying from phthisis. Precisely the same experience happened the other day to a medical man in a case into which he was inquiring, only that the facts were not remembered till a second visit was paid. There is, however, no difficulty for anyone who has previously studied the avenues of infection in making out many histories of exposure to infection. Indeed, I was able, after a second inquiry into deaths from tuberculosis in 1890, to show that a clear history of infection could be discovered in the majority of cases investigated, and to formulate the proposition that healthy persons, many of whom take phthisis, do not contract the disease except after prolonged and demonstrable exposure to infection. There are plenty of instances recorded in which infection has been probably traced from one person to another by inhalation and by direct inoculation, and which may be found scattered over the literature of tubercle. Thus, instances of infection by inhalation are given in Dr. G. A. Heron's book on the Communicability of Consumption; of inoculation of tubercle in Dr. Heron's book and in Dr. Senn's work on Surgical Tuberculosis; of inoculation in veterinary surgeons from cattle in Dr. Heron's book and in Arloing's "Leçons sur la Tuberculose"; and of infection of children by ingestion in Professor Delépine's paper on Tuberculous Infection through the Alimentary Canal. The evidence of infection in cattle and pigs is overwhelming, nor is it less so where sound people have been crowded together with the tuberculous under unfavourable circumstances. I venture to say that any intelligent man who may choose to put the necessary trouble into the work will be able to show a similar history of infection in any consecutive series of reasonably intelligent patients whose histories he may choose to investigate. It is true that this particular inquiry will give some trouble, and one needs, especially at first, to have a distinct faith that the facts will be revealed to the inquirer. To myself, personally, this knowledge came only after the partial failure of one investigation in 1886. But even on the first occasion the true relation of the facts had begun to show itself.

Now, we can show no such record of clearly traced sources of infection in respect of our ordinary infectious diseases such as typhoid fever, scarlet fever, and diphtheria, at all events in a large town. In the great bulk of instances no clear exposure to infection is made out. The reason of this is partly that many cases of these diseases are overlooked altogether, and partly that the avenues of infection are not clearly worked out. The bacillus of typhoid fever grows outside the body, and we do not know with sufficient precision where or under what conditions. We are not thus hampered in respect to tuberculosis. But we are hampered by the long periods of time which have often elapsed since infection occurred. In making such an investigation, therefore, we have first to ascertain when the disease definitely showed itself. We may then, in the case of phthisis in an adult, go back from one to two years for the source of infection. But the latent period is a very variable one. First, we ascertain whether any member of the same family with whom the person under investigation came much in contact was phthisical at such a period as was compatible with infection, or whether any intimate associate was affected. Failing in this we consider the occupation of the person, what materials he worked in, the nature of his work, and the possibility of infection among his co-workers. If he was working previously side by side with a sufferer from the disease, what were the conditions of the workroom? Were they such as to lead to the preservation, concentration, or dispersion of infective matter? It is necessary also to ascertain whether the phthisical person was originally of weak physique or had been weakened by any special cause. Had he sustained any injury? Under such circumstances a comparatively slight amount of infective matter may have been sufficient to produce tuberculosis. By these and kindred inquiries the facts will generally be elicited. The success of such an inquiry is ensured by the circumstance that tuberculosis is not an easily acquired disease by a healthy person, and that is why the etiological inquiry is so much more successful for tuberculosis than for other diseases, when pursued with ardour and persistence. The value of such etiological inquiries does not lie in the fact that they add to the proof that tuberculosis is a disease communicable and communicated—the experimental proof of this is such as to defy cavil; but the clear demonstration of the relation between the infector and infectee carries with it a conviction to most minds out of all proportion to its scientific value. Moreover, in this way we obtain a clear conception of the circumstances as regards personal condition, personal habit, circumstances of the dwelling, circumstances of work, and so forth, which determine the occurrence of infection, that we can get in no other way. The facts fall into their natural groupings. After such an investigation we are not disposed either to overrate or to underrate the influences of such factors as overcrowding, defective ventilation, adverse occupations, previous disease, and so on, and it can be seen that the one ever-present factor is a sufficient amount of exposure to infection, the amount differing according to the state of the individual, although, in preventing the disease from being communicated, other factors have, no doubt, to be taken into account. Nor is such an inquiry without individual results of importance. In my first inquiry in 1886 I was able to say that the most common period between infection and death was between two and three years—a period confirmed by Cornet's inquiry into the mortality of the Catholic nursing institutions. These inquiries also brought out the influence of alcoholism.

The record of Manchester work is already an excellent one in regard to the investigation of tuberculosis. For something like twelve years Dr. Arthur Ransome has advocated the instruction of tuberculous subjects in the methods of prevention, and no doubt a decided effect has been gradually produced on the public mind by the distribution of the leaflets of the Manchester and Salford Sanitary Association. A movement was also started by Dr. Ransome to disinfect the rooms occupied by tuberculous subjects, and also those in which such persons had died. This was, however, never prosecuted on any great scale, probably because the methods of disinfection were felt to be, at that time, insufficient. There was never in Manchester, be it said, anything approaching the notification of phthisis properly

Hosted by Google

understood. At the same time that Dr. Ransome was pursuing this object in Manchester we were distributing information in Oldham on the means of preventing the disease. This information was sent to every house in the borough, as has since been done in Manchester. This matter of popular instruction has been taken up with considerable vigour in Lancashire, and also, of late, in other parts of the country. Doubtless these instructions have produced an impression, though of what magnitude we have no means of telling.

Our chief contributions to the scientific knowledge of the disease in Manchester have come from Professor Delépine, as I do not need to say. Let me mention one or two points. Professor Delépine's observations have greatly helped in giving certainty to the view that the bacillus of human tuberculosis may be grown in suitable media at the ordinary temperature of the atmosphere, though such growth is very slow. He has added to our knowledge of the method of inoculation as a means of diagnosing tuberculosis. In conjunction with Dr. Ransome he has shown in an adequate manner that light possesses the power of destroying tubercle bacilli, a knowledge which had previously been in part assumed. By his investigations on the action of chlorinated lime he has furnished us with a cheap and efficient means of disinfection, which at the same time, in a proper degree of dilution, is quite safe. Dr. Harris's observations at the Manchester Royal Infirmary have added precision to the facts which show that tuberculosis is often recovered from, a matter of great moment both from the point of view of prevention and as regards treatment. I may also mention Dr. Kelynack's recent observations on the connexion of the occurrence of tuberculosis of the abdomen with cirrhosis of the liver due to alcohol. Dr. Dreschfeld's experiments on the ingestion of tuberculous meat may also be mentioned, though these do not so much concern us.

Notification of phthisis.—In the light of our existing knowledge it seems to me that, whatever the difficulties may be, we ought to try notification of tuberculosis. As I have already said, the cases which would be notified are all cases with tuberculous discharges and also cases of tabes mesenterica. What, now, are the difficulties to be encountered? The first difficulty is one of expense. No doubt the expense is an important matter for the health authority to consider, but it scarcely needs to be much considered here. I may say, however, that looking to the good which I believe we are certain to achieve, the money would be better spent than in regard to any other disease. As regards actual expenditure in notification fees, the average amount would not necessarily exceed that expended on all the other infectious diseases. There are, however, special difficulties attaching to this matter of notification. The duration of a case of tuberculosis is considerable, and the medical attendant is often changed in the course of the illness. If the full fee were to be paid to every medical man consulted by a tuberculous patient the expenses would amount to a large figure. To avoid this I propose to pay the fee only once. If the case were notified a second time by another medical man a small fee would be paid to cover expenses, while an intimation would be sent to him of previous notification with all particulars. Notification would, however, be compulsory. As regards public institutions, it is necessary to remember that a certain number of the cases would not previously have been seen by a medical man. The names and addresses of the cases should, therefore, be recorded and forwarded to the health office, say, once a week. For this service a small annual sum might be paid.

What, then, might we hope to obtain from notification of cases of tuberculosis? In the first place, we should have a continuous record of the persons affected, of their addresses, and of the places where they carried on their employment, or of the school or other daily resort of the person reported. Such a continuous record would clear up many dark places in the history of the propagation of the disease, and would enable us to know precisely where to apply a greater urgency of precautions. In the second place, it is incontestable that the propagation of tuberculosis is much furthered by the adjuvant influence of certain insanitary conditions, by overcrowding, by damp, dark, and ill-ventilated dwellings, and by other influences which would come under the scope of an inquiry instituted by the health office. These conditions it would be the business of the health department to ascertain and remove. In the third place, notification would enable us to deal in an adequate manner with the personal precautions required to be taken by the patient to avoid infection. At present we have no means of knowing to what extent such personal precautions are enjoined by medical men, and I am afraid it is quite certain that they are to a large extent neglected. The proposal is that the health office should coöperate with the practitioner in getting necessary precautions carried out. A certain degree of constraint would necessarily arise in this manner. Inquiries would be made from time to time by the representatives of the health office, on forms prepared for the purpose, of the actual steps taken by the person affected to protect the members of his family and his fellow workers from infection, and an effort would be made to induce phthisical people to carry out necessary precautions, such as those relating to the interception and removal or destruction of sputum at home and in the workshop. As Cornet has abundantly shown, sufferers from tuberculosis, in the absence of such precautions, are a serious danger to their neighbours as well as to themselves, but, if the necessary precautions are carried out, they need not endanger anyone. It is, therefore, not at all necessary to deprive the phthisical of their employment, but it is, on the other hand, remarkable how long they have been allowed to endanger and endamage others. All this needs, however, to be carried out with discrimination, although I do not foresee any great difficulty, if much labour, in obtaining what is needed by the joint action of the medical attendant and of the health office. In the fourth place, as an auxiliary means of defence, it is necessary, especially where you cannot be sure that a strict personal hygiene has been carried out, to have the rooms occupied by tuberculous persons disinfected. The extent to which this is necessary cannot be gauged until, by careful and sufficient observation, it has been ascertained to what extent personal hygiene can be secured. With strict personal hygiene repeated disinfection is not needed. With less strict personal care, such as must often inevitably occur in the last months of life, it is more necessary. Disinfection should be carefully carried out after the death of a phthisical person. Especially is this the case where, as with lodgings, the room is certain to be speedily used by some other person, probably healthy. Besides the advantage of dealing directly with the insanitary conditions which I have mentioned, much valuable information may be obtained in regard to the previous health, habits, and circumstances of the tuberculous which may be supposed to determine the risk of infection. Here, again, the coöperation of the medical attendant would be indispensable. In fact, there is no doubt that to bring a system of notification into successful working implies an even closer relationship between the medical attendant and the health office than now exists. It will be manifest that much work will be thrown on the health office by the notification of phthisis. In order properly to present and utilise the facts of notification it will be necessary to be able to refer at once to the name, address, and principal facts for any case previously reported. This can be done, but it means a good deal of clerical work. The uses to which notification may be applied do not, at present, admit of complete arrangement. They may be presented in a rough shape, but trial alone will enable us to see how the administration will work out. Phthisis stands precisely in the same position now as did scarlet fever, &c., before notification came into force. The only difference is that the problem is larger. Infection in the case of tuberculosis is more easily traced, our knowledge of the precautions necessary is more certain, and our opportunities of usefulness are infinitely greater and more assured. Otherwise there is no difference, except as a matter of administration, between tuberculosis and other notifiable diseases.

There is one scientific question connected with tuberculosis which, perhaps, needs some consideration—viz, the question of heredity. Were tuberculosis congenital, or were there any tissue tendency towards tuberculosis, it might be maintained that our endeavours to prevent tuberculosis would, to some extent at all events, be thereby baffled. There is, however, no reason for supposing that tuberculosis is congenital, except to a trifling extent. As Koch pointed out in 1882, the lesions of tuberculosis are such that the idea of a latent tuberculosis is scarcely to be entertained. Visible lesions of tuberculosis at birth, however, are very rare, and when they do occur point to infection from the mother through the placental circulation. Moreover, statistics given by Professor Delépine in his paper on Tuberculous Infection through the Alimentary Canal show that the records of post-mortem examinations

Hosted by Google

available give an almost complete absence of observed tuberculosis in the first two or three weeks of life, the numbers increasing slowly, and then rapidly as the age advances. It is the same with calves. The absence of an inherited latent tuberculosis is further shown by the facts relating to the guinea-pig, the young of which animal, when the mother is tuberculous, is almost never tuberculous, and if reared apart does not become so. Bang's experience with calves is the same. As regards an inherited tissue tendency, we have the facts above mentioned and others of a more general nature, such as the great mortality among healthy people when exposed to intense infection, and also in healthy animals under the same circumstances, and the manner in which the disease has been shown to overrun new populations when freshly introduced among them. Indeed, it would almost seem that infected populations possessed a certain degree of tissue immunity. This conception is strengthened by the large proportion of recoveries from phthisis which we now know to exist, coupled with the temporary refractoriness to tuberculin which is set up after a short course of inoculation. If the recent announcement of the isolation in Koch's laboratory of an immunising body in the bodies of tubercle bacilli be confirmed, this view would be much strengthened. There would remain in that case only the inheritance by the children of tuberculous persons of a weak physique.

Another subject of much importance is the diagnosis of the disease. We have already valuable and much-needed aids in a correct appreciation of commencing tuberculosis. Where a discharge exists we have microscopical examination of the discharge and the extremely delicate test of inoculation, which, however, can only be made in a pathological laboratory. We have also in non-febrile conditions the use of minimal doses of tuberculin, the danger of which is probably not great and which may even be to some extent curative. Finally, we learn from Professor Delépine's paper in the *Medical Chronicle* of April that we may look for a test similar to that now employed for typhoid fever. It would thus seem that we are approaching a period when no error need exist even about living persons, and when, therefore, we may proceed with increased confidence in our preventive measures.

Manchester.

THE PRESENT ASPECT OF THE TREATMENT OF CONGENITAL DISPLACEMENT OF THE HIP.

BY A. H. TUBBY, M.S. LOND.,

ASSISTANT SURGEON TO, AND IN CHARGE OF THE ORTHOPÆDIC DEPARTMENT OF, THE WESTMINSTER HOSPITAL; SURGEON TO THE EVELINA AND NATIONAL ORTHOPÆDIC HOSPITALS.

THE treatment of this disabling deformity is one that at present exercises the minds of surgeons considerably, because hitherto no particular method has been found to be uniformly successful, and at this time the subject is passing through a transition stage. It is now felt by those who have most experience of the treatment of this affection that operative measures in a wide sense are very far from attaining satisfactory results, and there is, so to speak, a throw-back of opinion in favour of the treatment first initiated by Paci—namely, forcible reduction and the maintenance of the limb in the abducted position. Before going into details it will be advisable, first, to review the various phases through which treatment has passed. There is, however, one considerable difficulty in deciding which is the appropriate treatment for cases, and that is the comparative scarcity of specimens in museums from which to gain definite conclusions. But it would seem that certain factors are always present at birth in truly congenital cases—namely, the acetabulum is, as a rule, in its normal position, though abnormal in shape, being triangular, oval, or elongated, yet very seldom absent.

In early cases, notably those described by Lockwood, the cartilaginous rim is wanting and the mass of fat at the fundus of the acetabulum, the gland of Havers, is much hypertrophied. When the cotyloid border is defective the cavity is almost continuous with a flattened surface on the iliac bone, sometimes covered with cartilage, indicating the new position taken by the displaced head. The head of the femur is round, or irregular, or flattened. In some cases it is said to have been absent even at birth, but this fact is not well authenticated. The neck is short and conical, and forms an angle rather less obtuse than normal with the diaphysis. The round ligament is flattened and slender, or in many cases is absent. The capsule is elongated, thinned, its capacity much increased, and sometimes it is distended with fluid. There is often considerable displacement of muscles, and Lockwood has stated that those which surround the joint participate in the disturbance of position, the obturator externus and quadratus femoris being dragged upwards by the ascent of the head of the femur. The ilio-psoas lies in a deep groove which is situated just below, and internal to, the anterior inferior spine of the ilium, and the tendon of the psoas winds backwards in an exaggerated way to reach the lesser trochanter. Such are the appearances often seen, and the points to be recognised at this early period of life are the abnormal shape of the acetabulum, its shallowness, and the frequent deficiency of the cartilaginous rim around it. In children who have walked the acetabulum is seen to remain small, shallow, and triangular. Above and posterior to it and around the new socket there is sometimes found a growth of bone, which forms a partial rim for the new socket and to which the capsular ligament is attached. The neck of the femur may be shortened or absent, and then the head is supported directly by the shaft, but in other cases the neck is still quite distinct, and an important point is the change in its direction. In cases in which the displacement is dorsal the neck is, as it were, bent backwards; in cases of anterior displacement it is bent forwards, so that it no longer forms a proper angle with the shaft. This is an important point in the question of treatment by manipulative measures, as in some cases, while it is quite possible to get the head in a good position, the whole limb and the foot remain turned outwards or inwards, as the case may be. The capsule is elongated, dilated, and in some cases thinned, while in others it is much thickened. It sometimes has a curious hour-glass shape and its cavity is constricted about the middle. The muscles are stated to be contracted considerably, and their contraction in some cases forms a distinct hindrance to reposition of the head of the bone. In adult life these changes are much exaggerated, but Bradford and Lovett remark that the new cavity on which the head of the femur rests is often deep enough to form a good support. The pressure of the head of the femur in its new position causes absorption of the periosteum and redundant joint-capsule in that place, and the capsule finds a new attachment in the osteophytes thrown out to form an upper rim to the new cavity in favourable cases. Muscular contractures around the joint are best seen in adults, and they are no doubt due to the abnormal position of the head of the femur and to the slight flexion and rotation of the thighs. Considerable shortening is found in the psoas and iliacus and in the peri-trochanteric muscles, while the adductors and internal rotators are affected in an equal degree. Such, then, in brief, are the essential departures from the normal which are found at birth, during childhood, and in adult life.

The methods of treatment of congenital displacement of the hip are three—namely: (1) extension, either in the recumbent position or by apparatus; (2) operative measures; and (3) forcible reduction.

1. *Extension, either in the recumbent position or by apparatus.*—This is the oldest form of treatment, and among its advocates are Pravaz, Buckminster Brown, and William Adams. But to Buckminster Brown should be ascribed the credit of having from the first treated cases in this way with considerable success. He subjected his patient, a little girl, aged four years, to complete recumbency with extension for thirteen months and then allowed her to get about for a year in an apparatus by which she could imitate the movements of walking without bearing the weight on the legs. At the end of two years and three months the trochanters were in place, lordosis had disappeared, and the child was able to run about normally. Unfortunately, the patient, when seen nine years after the conclusion of treatment, had lapsed. In this country Mr. William Adams has advocated this method of treatment, and his experiences are recorded.[1] But, unfortunately, we are not told that the patients were able to get about ultimately

[1] Brit. Med. Jour., Feb. 22nd, 1890

Hosted by Google

without apparatus of any kind. I have tried recumbency with extension in two cases with much promise of success, but at present the patients are getting about and walking with an extension apparatus on, and I am waiting until the apparatus has been off for a year before reporting the cases. Sometimes, where it is not possible to submit the patients to prolonged recumbency, I advise the following modification of this treatment—namely, the use of weight-extension at night and the wearing of an extension-instrument by day, the patient being allowed to walk about at will. This plan is very useful in children under four years of age, but is not successful in older children.

2. *Operative measures.*—Those most in use are Hoffa's and Lorenz's. The details of Hoffa's operation are sufficiently well known; it is very severe when carried to its full extent. It almost amounts to amputation at the hip-joint, the femoral artery and vein, the anterior crural and the sciatic nerves alone being left intact, and there is wide and deep gouging of the bone at the site of the deformed acetabulum. Personally I am strongly of opinion that it is not advisable to persuade a patient to undergo Hoffa's operation, because of the unsatisfactory results by which it is so often followed. Hoffa details the results of 112 operations by him on 82 patients; 30 of them had bilateral and 52 unilateral displacements. Death occurred in 3 cases, in 2 of them being due to prolonged anæsthesia, hæmorrhage, and shock, and the third to iodoform poisoning. In 9 cases ankylosis of the hip followed, and return of luxation in 11. Dr. Halsted Myers, in the "Annals of Surgery," August, 1895, remarks that he has notes of 177 cases of Hoffa's operation, or some of its modifications, and amongst these are 6 deaths due directly to operation—namely, 3 of Hoffa; 2 of Kirmisson, 1 from hæmorrhage and peritonitis, eight days after the operation, following perforation of the acetabulum, and 1 from septicæmia; there is 1 death in a case operated on by Broca. Kirmisson states that he knows of a few fatal cases in the hands of other surgeons which he is not authorised to mention. Another point that militates against Hoffa's operation is the fact that cure is by no means certain. Hoffa has himself stated that he wishes it to be distinctly understood that these children cannot be completely cured, since there is always left some shortening of the limb. In bilateral cases, however, he can reduce the waddling gait to a minimum, and can almost overcome the lordosis.

The details of Lorenz's operation are: Division of the tensor vaginæ femoris through a longitudinal incision starting from the anterior superior spine of the ilium, and to the first incision is added another passing transversely inwards at the level of the trochanter; the anterior wall of the capsule is then denuded and the capsule opened by a crucial incision, the acetabulum is hollowed out, and the head of the femur re-formed if necessary; after which it only remains to pull on the latter until it is brought down to a level with the cotyloid cavity; much assistance is now afforded by section of the ham-strings. Lastly, the limb is put up in a position of slight abduction; in four weeks' time massage and gymnastic exercises are begun, and these must be continued for a year. The advantages of this operation consist in causing comparatively little interference with the muscles. In Dr. Halsted Myers's paper in August, 1895, in the "Annals of Surgery," on Congenital Dislocation of the Hip, it is there remarked that Lorenz had then operated on 63 cases and had recorded no deaths and but 3 relapses. Since then Lorenz must have found much cause for modifying his opinion of the value of his operation, as "after much thought and careful observation of the cases he has operated on he resolved to alter his procedure in many cases," and has carried out bloodless reduction with perfect success. This statement coming from so experienced a surgeon as Lorenz, from one who has devoted himself so much to the subject, is worthy of the greatest consideration. But before Lorenz had arrived at this conclusion other surgeons' thoughts were drifting in the same direction. For instance, Professor Schede of Bonn, who has had experience of treating such cases in two ways, either by the operative method or by the method of rest combined with extension and abduction of the limb, reported very favourably of the latter method.

3. *Forcible reduction.*—Paci's manœuvres are carried out as follows. The patient lying down, the surgeon flexes fully the leg on the thigh, and the thigh on the pelvis. This movement carries the head of the femur downwards, especially when assisted by direct pressure. The thigh is now abducted slightly. After this the limb is strongly rotated outwards, and then rather more rapidly fully extended. The last movement throws the head of the femur into, or on, the acetabulum. Paci in 1894 reported on 15 cases, and they were almost perfect a year or more after operation. With the idea of more effectually fixing the head of the femur in its new position or into its proper position, Lannelongue advises the injection of a few drops of a 10 per cent. solution of chloride of zinc at intervals of three or four weeks. This method has answered very well. Lorenz has modified Paci's method, and his present procedure is as follows: First, lowering the head of the femur by traction. Secondly, depressing the head of the femur to the utmost degree by flexion, followed by forcible abduction. The penetration of the head into the cotyloid cavity is announced by a perceptible shock and click. Thirdly, fixation of the femur by a plaster-of-Paris bandage, which prevents reproduction of the dislocation. The plaster-of-Paris treatment should be continued for several months. Lorenz has now employed this method of treatment in 43 cases, aged upwards of six years, and met with success in every case. No apparatus was ever used after the treatment was finished. As a modification Mikulicz employs an apparatus by which extension is made after the reduction, together with considerable abduction, and the head of the femur is pressed firmly into its new position.

It would seem, then, that of the three methods that have been described that of recumbency with extension, although fairly well tried, has not been quite satisfactory; that of open operation — namely, Hoffa's method — is somewhat dangerous, is by no means perfect in its result, and cannot be relied upon, while that of Lorenz, although less severe, yet also cannot be said to be quite perfect, nor can the originator of that operation admit that he himself is quite satisfied with it, while there is to be noted the sudden change of his opinion in favour of the third measure—namely, forcible reduction. For my own part I have been quite unable to convince myself that it is possible, in the first place, to deepen an imperfect and shallow acetabulum in such a way that the head of the femur can be retained in spite of all the shocks of body movement and weight that it has to bear. Nor in the few cases of Lorenz's operation which I have seen has the result been in any sense satisfactory—either the lordosis or some up-and-down movement has remained, or, as in one case I saw, there was bony ankylosis. This was a young girl, aged thirteen years, who went over to Vienna to be operated upon and came back to show herself to me afterwards. I found firm bony ankylosis of the left hip, surely a very serious occurrence in view of the future possibilities of marriage and pregnancy. Nor do I think that those cases which have been operated upon in England have in any sense satisfied the surgeons that Lorenz's procedure is to be relied upon, or that they have a distinct curative value.

In support of these views is the following abstract from the *Sammlung der Gesellschaft Deutscher Naturforscher und Aerzte*, 1896. Professor Schede, who initiated the discussion, stated that out of a total of 99 cases he had in 98 successfully reduced the dislocation by external manipulation. The ages of the patients ranged from infancy to fifteen years. In children who had not learned to walk the reduction was accomplished under chloroform by simple traction on the limb with the thigh abducted. A return of the displacement was prevented by a plaster-of-Paris bandage, which maintained the abducted position of the limb and at the same time exercised pressure upon the trochanter. In all the children where this simple procedure failed it was necessary to make repeated attempts, and especially to overcome in the first instance by means of extension the resistance offered to the reduction by the contracted soft parts. After reduction in unilateral cases, if the child had learnt to walk, he was allowed to go about in a plaster bandage. But inasmuch as the abducted position results in apparent lengthening of the affected limb, the sole of the sound foot must be heightened to a corresponding degree. In bilateral cases it is strongly urged that both dislocations be reduced at one sitting. The thighs are maintained in an abducted position by a plaster bandage like a pair of bathing-drawers—that is, it stops short at the knees. The bandage should be worn for from four to six months. Lorenz formerly the advocate of operative treatment, continued the discussion, and stated that he had been successful in securing reduction by external manipulation in 83 cases. He drew attention to the value of first employing some method of extension whereby the displaced head of the femur can be drawn down to the level of the acetabulum. The joint is then fixed in

Hosted by Google

the abducted position until the shorter adductor muscles are sufficiently stretched to allow of the surgeon proceeding to the actual reduction. This latter is accomplished by flexing the thigh to a right angle, and while traction is made in the long axis of the thigh the latter is abducted until the head of the bone enters the socket with a characteristic click. The head may then be felt in its normal position in the inguinal fold midway between the anterior superior spine and the symphysis pubis, while at the same time the thigh becomes visibly longer.

The advantages of securing reduction by manipulation instead of by operation are obvious, apart from the avoidance of risks appertaining to all major operations. There is no scar, there is no possibility of later contracture or of osseous ankylosis, and the after treatment is so simple that children may be treated as out-patients. Operative measures may therefore be said to be restricted in the future to cases in which the manipulative procedure has failed after repeated attempts. Hoffa of Würzburg, Wolff of Berlin, and Kümmel of Hamburg corroborated the opinions expressed by Schede and Lorenz.

It seems, then, that we have reached this position—that operation either by Hoffa's method or by Lorenz's method must be considered seldom necessary, and it is entirely discredited as a means of treating every case of any severity, and that it can only be used as a last resource, and then with no certainty of success, but at considerable risk to the patient. At almost any age up to adult life the manœuvres of Paci, as modified by Lorenz, will be found to afford the best method of treatment. So far, then, we have not attained to any ideal form of treatment of this serious deformity, and the matter must remain for the present in an incomplete stage, but the best we can offer the patient is forcible reduction without an open wound, with the prospect of cure in many cases and of much improvement in others.

Weymouth-street, W.

ON SERUM DIAGNOSIS IN GLANDERS.

BY ALEXANDER G. R. FOULERTON, F.R.C.S. ENG., D.P.H. CAMB.,

IN CHARGE OF THE BIOLOGICAL CHEMISTRY LABORATORY, BRITISH INSTITUTE OF PREVENTIVE MEDICINE.

ALTHOUGH Professor M'Fadyean of the Royal Veterinary College called attention some five months ago to the fact that the serum from a case of equine glanders caused well-marked agglutination in bouillon cultures of the glanders bacillus, no record has hitherto been made of the serum reaction in human glanders. In Professor M'Fadyean's case the serum was diluted with nine times its volume of sterile bouillon and then mixed an equal volume of a bouillon culture of the bacillus. The proportion of serum used was thus one in twenty, and "the reaction was quite distinct after an hour, and at the end of two hours almost the whole of the bacilli had become motionless and collected into large irregular clumps."[1]

In February last I was enabled by the kindness of Mr. Atkinson, house surgeon at King's College Hospital, to investigate thoroughly the serum reactions in a case of glanders occurring in a stable-boy who had been admitted under Mr. Rose. In testing this serum a bacillary emulsion was made as follows. Five c.c. of a 0·5 per cent. sodic chloride solution were added to a five days' old culture of the bacillus on glycerin-agar; the contents of the tube were shaken up gently and then allowed to stand for about an hour in order that any small particles visible to the naked eye might settle. The upper part of the fluid was then pipetted off and the emulsion thus obtained was found to be in every way suitable for the experiments. The bacilli used were of a stock isolated from pus derived from the patient in question. Using hanging drop preparations, in which the proportion of serum to bacillary emulsion was as one to nine, it was found that large clumps always formed before the specimen could be transferred to the stage of the microscope for examination. With one part of serum and nineteen of the emulsion a similar agglutination invariably occurred within ten minutes. Thus the human serum would appear to act more energetically in this respect than does the equine serum as described by Professor M'Fadyean. The agglutinative action of the serum was equally well shown in test-tube experiments. Two series of these experiments were carried out, in one set 0·2 c.c. of the serum with 2 c.c. of the emulsion and in the other 0·1 c.c. of the serum with 2 c.c. of the emulsion being used. There was no appreciable difference in the appearance of the tubes in the two sets of experiments. In either case the upper part of the emulsion began to clear in about six hours, and at the end of twenty hours there was complete sedimentation of the bacilli, which formed a coherent mass at the bottom of the now otherwise clear fluid. Several samples of normal human serum used in the proportion of one part to nine of the emulsion caused no change whatever in the bacilli, whether in hanging drop preparations or in the test tubes. Professor M'Fadyean notes that the same is true of normal equine serum. So far the results of the experiments were quite satisfactory, and in accordance with what has been found to be the action of the serum from cases of cholera, typhoid fever, and diphtheria upon the respective bacteria causing these diseases. But on further investigation it became apparent that this agglutinative action of the glanders serum could not be said to be a specific one so far as the glanders bacillus was concerned, for on repeating the above experiments with a similar bacillary emulsion, but substituting for the glanders serum first anti-diphtheric serum (1 c.c. = 300 normal units) and then four different samples of serum from cases of typhoid fever, it was found that equally well marked agglutination of the glanders bacilli occurred. Similar results were also obtained with bouillon cultures of the bacilli; and it is almost unnecessary to add that control experiments were made throughout.

The result of all this may be summed up as follows. Agglutination of the glanders bacillus can be brought about by contact with (1) a serum from a case of active infection by the glanders bacillus; (2) a serum from a case of active infection by the typhoid bacillus; and (3) a serum from a horse immunised against the diphtheria bacillus. And, on the contrary, no such action is manifested by either normal human or normal equine serum. On reversing the experiments it was found that a certain, though decidedly less active, agglutination of the typhoid bacillus was caused by both anti-diphtheritic serum and glanders serum. With regard to these latter experiments I do not propose to offer any comments now, as I hope to deal fully with them in a paper in the forthcoming volume of Transactions of the Institute of Preventive Medicine. From the above it will be readily seen that the value of the serum reaction in glanders as an aid to clinical diagnosis is extremely doubtful.

As to the interest and immense importance in its bearing on various problems affecting bacterial diseases of the work on serum reactions which we owe to Pfeiffer, Grüber, and Durham there can be no question. But the application of their results for purposes of clinical diagnosis is quite another matter. And without wishing for one moment to underrate the very valuable work in this direction which has been carried out more especially by Widal abroad and in this country by Sheridan Delépine, I would venture to suggest that the absolute specificity of serum agglutination in different diseases has yet to be proved. Indeed, it appears to me to be, in the first instance, most unlikely that the unknown substance which in the serum of typhoid fever—to take that disease as an example—exerts so potent an influence on the typhoid bacillus should be inert as regards other bacteria. One is therefore not surprised to find that the equally unknown, but probably similar, substance in anti-diphtheritic serum has an agglutinative action on both the glanders and typhoid bacilli.[2]

Carlisle-mansions, S.W.

[1] Preliminary Note on the Sero-diagnosis of Glanders, Journal of Comparative Pathology, December, 1896.

[2] With regard to the anti-diphtheritic serum it must not be forgotten that Bordet found that agglutination of typhoid bacilli was sometimes observed with normal equine serum. But normal equine serum has, as already stated, no action of the sort on the glanders bacillus.

THE NEW ELTHAM COTTAGE HOSPITAL.—A dramatic performance will be given on Monday next, May 3rd, at 8.30 P.M., at St. George's Hall, Langham-place, on behalf of the hospital. The play to be performed is the ever popular *Dan'l Druce*. Tickets may be obtained through Mr. Jeken, Bexley-road, Eltham; Dr. Mitchell, Court-road, Eltham; Mr. White, High-street, Eltham; Mr. J. Eagleton, West Chislehurst-park; Mr. E. Hesketh, Court-road, Eltham; Mr. E. R. Sharpe, Court-road, Eltham; and Mr. W. G. Cowell, High-street, Eltham.

A CASE OF POISONING BY QUININE.

BY GEORGE GRESSWELL, M.A. OXON., L.R.C.P. & S. EDIN., L.F.P.S. GLASG.

I WAS summoned to attend a woman said to be in a fit, and found her at about 11 A.M. prostrated, unable to speak, and with a pallor on her countenance like that of impending death. My first impression was that it was the first stage of a very bad case of influenza, and my second that there had been an apoplectic stroke. Inquiry, however, and further observation soon convinced me that the symptoms were to be referred to a large dose of quinine which had been taken before breakfast. The subject was a woman, aged forty-seven years, and for the last three months there had been no menstruation, the climacteric having, no doubt, supervened. She had just vomited about a quart of what she had taken for her breakfast. When the window and door had been opened, and the patient had been placed in a recumbent posture on the sofa, it was not long before she revived a little, and the pulse and heart-beats showed a very slight improvement, as also did her general aspect, but not in any way markedly until after some hours had elapsed. It appeared that she had taken at least about two teaspoonfuls of quinine (sixpennyworth), and probably more, which she had dissolved in a pennyworth of acid, and soon afterwards had taken her usual breakfast. She then seemed unwell, but, in reply to her husband, said she should soon be all right again. As, on the contrary, she rapidly became worse, and seemed to be in a fit, he became sufficiently alarmed to send for me. When I arrived, her hands and face were extremely pale, the pulse was very quick and irregular—almost fluttering, small, thready, and feeble. The number of beats per minute was well over 120. The heart-sounds, though clear, were of little strength, and had a dull, subdued, metallic character, and yet, though weak, possessed at once a greater vigour and regularity than could have been inferred from the pulse. It is, of course, often the case that very erroneous conclusions regarding the central circulatory power may be drawn from an observation of the radial pulse of both sides. Until about 5 P.M. the patient remained speechless and quiescent, but, as she afterwards informed us, not quite unconscious, although she appeared to be so. On the following day she said she had known something of what was going on around her, but had been unable to speak or hear, and she said she saw me during my second visit. She had been sick several times until about 5 P.M., when, on being asked if she would have some tea, she replied that she would like some. It was about 6 30 P.M. that I saw her for the second time and found her general condition improved. There was a little colour in her cheeks. The pulse was fuller and quieter, but still numbering 108 per minute. Her heart-sounds were stronger, the cardiac muscle evidently having recovered some of its former power. She was still very deaf. The pupils were rather contracted, and, though they reacted to light, did not do so with much readiness, dilating only slightly. The tongue was throughout clean. She said she had no pain and no headache, but a feeling of uneasiness in the throat. She had taken a little brandy and lemonade, but I ordered her to have no more. By inquiry on the following day it was elicited that she had had a queer feeling of faintness about a fortnight ago, and then again about a week ago, but these attacks were described so vaguely that very little account could be taken of them. Some medicine had been given which had helped in producing a sufficient amount of vomiting, although the patient would probably have vomited without the medicine, and no doubt had thrown up the greater part of the quinine. A little calming medicine gave her a good night's sleep, and she awoke refreshed and very much better in the morning. She had again had a little lemonade and brandy. I saw her at noon on the day after the dose, having received a good report of her early. She was able to talk, though she was still deaf, especially in the right ear. She had had a motion on the previous day, but I thought it well to give an aperient pill containing a grain of calomel. The pulse was fairly full and regular, and there was colour in her cheeks. She had had some gruel, and was still recumbent. The tongue was clean but parched, and had little obliquely transverse furrows. Although still weak, she had evidently so far recovered that no further danger was to be apprehended.

On the Wednesday after the Sunday on which the quinine had been taken the patient was again seen in the afternoon. The pulse was then 72, her general condition was greatly improved, yet the heart's action was still feeble and there was a slight presystolic murmur. She was in bed, and had been during the Tuesday. She had taken no solid food. The bowels had acted. There were little furrows on the tongue. The deafness had almost entirely left her. On the following Saturday the patient looked almost quite recovered. The pulse was normal in number and fair in character. The pupils were a little larger, but yet did not react well. There was a slight presystolic hesitation. On the last occasion of seeing her, thirteen days after the above Saturday, her pupils reacted well. There was no deafness. The cheeks had a little colour. The respiration and pulse were good and the heart-sounds were very fair. In describing the onset of her symptoms she said that she first felt faint, then dizzy, was then sick, and then felt "tinglified" in her fingers and all over, and then unconscious and without pain. The deafness was complete and came on rather suddenly, as if from a blow. She heard nothing before the clock striking twelve at night, and that only with the left ear. For some days she was slightly deaf in the right ear. She had been able to see, but did not apprehend the nature of objects until about 4 o'clock in the afternoon.

Although I have attended on previous occasions persons who have taken quinine for ague and malarial fevers in rather large doses, this is the only case of quinine-poisoning I have ever had under my care.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF RUPTURE OF THE HEART.

BY WILLIAM GROOM, M.D. CANTAB.

ON Good Friday morning I received a message to see a lad, aged sixteen years, who, whilst walking with his brother, suddenly fell on the pathway face downwards and was removed to a house close at hand. On my arrival I found him to be dead. The coroner for the Isle of Ely directed me to make a post-mortem examination and attend the inquest, at which the brother in his evidence informed us that about a month previously he and the deceased were at Sutton Bridge hawking fish with a pony and trap; the pony took fright, his brother tried to stop it, and the shaft of the trap pressed him on the chest against some wooden railings. In consequence of this deceased had to stay at Sutton Bridge for five days, and was attended by Mr. Wellington; he then returned home, but remained weak and unwell. At the post-mortem examination no signs whatsoever of injury to the superficial structures or ribs were found; but on opening the pericardium I found it to be filled with blood, some of which was clotted. On removing this, and on turning the heart over without detaching it, I discovered a hole about the size of the end of my little finger through the middle of the back wall of the left ventricle, the actual size of the rupture being about the third of an inch. On removing the heart and opening the ventricle I found the walls to be perfectly sound except at this spot; the hole was quite conical and bulging when my little finger was introduced, and the rupture external and merely consisting of the pericardial covering of the wall. In my opinion, therefore, the accident had caused a partial rupture of the inner part of the wall of the left ventricle (endocardium and some muscle fibres) at a spot opposite to the point on which the shaft of the trap pressed, that the blood pressure had, during the month intervening between the accident and death, caused an aneurysmal bulging of the weakened part, its wall becoming thinner until ultimately it burst. The rupture, seen from the interior of the ventricle, looked much like a bullet hole. Taking into consideration the whole of the facts connected with this case I consider it sufficiently interesting to place

Hosted by Google

on record. I have sent the heart for preservation to the Anatomical Museum at Cambridge.

Wisbech.

CHRONIC SENILE DIARRHŒA, PROBABLY FROM DEGENERATION OF THE INTESTINAL WALLS.

BY A. J. B. DUPREY, M.R.C.S. ENG., L.R.C.P. LOND.

DEGENERATION is not uncommonly in persons past middle life the source of various uncomfortable symptoms, and in a tropical country such as that of Trinidad, where old age is to some extent premature, we may expect to find senile troubles manifested sooner than in colder climates. Not unfrequently we meet with cases of diarrhœa in persons approaching or beyond sixty years of age, which can only be ascribed to degeneration of the intestinal walls, due either to albuminoid disease or to some perverted action presumably associated with degeneration. The patient whose illness I am about to describe was a female fifty-six years of age and was a member of a family one of whom I had been attending only a few days previously for poisoning by alkaline ptomaines, an accident which not unfrequently occurs in these parts. She had always enjoyed good health until about twelve months ago, when a small tumour, the nature of which was not properly ascertained, was removed from her nose. About nine months ago she observed an undue looseness of the bowels, since which time she had had three attacks of diarrhœa, each of them more severe than the preceding one. The present attack was therefore the fourth. When I first saw her, her temperature was 101·2° F. and her pulse 84; the heart's area was normal; the sounds were very feeble, but no abnormality in the rhythm could be detected; there was dimness of sight and well-marked arcus senilis of both eyes; the tongue was slightly furred. The patient retched very often and occasionally vomited; she also complained of great pain in her abdomen; it was tender on pressure, and she passed fluid evacuations at intervals of twenty minutes or half an hour. As there had been cases of ptomaine poisoning in the house I considered this illness to be of the same kind, and ordered brandy milk with soda water, and a mixture containing bismuth sub-carbonate and nepenthe. During the next twenty-four hours the diarrhœa was less frequent, but symptoms of cardiac failure were developed, so urgent that death appeared to be imminent. The patient had repeated attacks of fainting, sometimes at intervals of fifteen minutes; her skin was almost icy cold, her lips were livid, and the pulse at the wrist was scarcely perceptible. I was at this time informed that she had suffered from fainting fits during her previous attacks of diarrhœa, although never so seriously as at present. Taking into consideration the marked degeneration of her corneal tissue shown by the arcus senilis, her dimness of vision, the failure of the circulation, and the chronic diarrhœa, I came to the conclusion that degeneration resulting from senile changes might have originated her troubles. Artificial warmth was supplied by hot-water bottles and flannels wrung out of hot water; a mixture containing five drops of tincture of digitalis and twenty drops of spirit of nitrous ether was given every four hours and improvement commenced immediately. When she was able to walk about the room five drops of tincture of strophanthus were given three times a day in place of the digitalis; and except for a slight giddiness on getting up in the morning she has satisfactorily recovered. There can be little doubt about either the degeneration of her heart muscle or the prompt efficacy of the digitalis in strengthening the heart's action, and thereby improving the circulation.

Port of Spain, Trinidad, West Indies.

A CASE OF RECURRENT SCIRRHUS OF THE MALE BREAST.

BY SELBY W. PLUMMER, M.D., B.S. DURH.,
HONORARY SURGEON TO THE DURHAM COUNTY HOSPITAL.

A MAN, aged thirty-nine years, was admitted in March of this year under my care into the Durham County Hospital. He gave the following history. Eight years previously he had noticed a small lump in his right breast, which slowly increased for four years. Although painless itself, shooting pains ran down the right arm from it. In January, 1893, this tumour was removed by Dr. Tough of Crook, County Durham. In 1895 the patient again noticed a hard nodule on the upper and outer part of the right chest, which gradually increased, and similar shooting pains were felt down the arm. This growth was freely excised and proved to be a typical scirrhous carcinoma invading a gland. Dr. Tough, having preserved the specimen which he excised, kindly sent it to me for examination, stating that the size on removal was about that of a pigeon's egg, and sections of this specimen showed it to be a scirrhous carcinoma of the mammary gland.

Notes of cases of cancer in the male breast are, I think, always interesting. It should be added that two of this patient's cousins on the female side died from cancer; in one the growth was located in the breast and in the other in the rectum. There is no other family history of predisposition.

NETLEY HOSPITAL.

A CASE DEMONSTRATING THE APPLICATION OF THE ROENTGEN RAYS TO MILITARY SURGERY.

(Under the care of Surgeon-Colonel STEVENSON and Surgeon-Major H. R. WHITEHEAD.)

THE localisation of bullets has always been a matter of great difficulty, and the majority of the older surgeons refused to attempt the removal of a bullet if it were deeply placed; and in this they were fully justified, for the difficulties and dangers of deep dissections were so great that the patient as a rule ran less risk if nothing were done. By the electrical method employed to a slight extent of late years somewhat vague information could be obtained as to the whereabouts of a deeply-seated bullet, but it was not until the introduction of the Roentgen rays that a surgeon could be quite certain of the exact position of the projectile, and in no case is the surgical value of the x rays more obvious than in this. The opacity of a body consisting of lead is so much greater than that of bone that the shadow cast by it is readily discernible, even when the leaden body is entirely surrounded by osseous tissue. It will be seen in the description of the case that the exact position of the metallic body was ascertained by taking two skiagraphs from different aspects.

The patient was a private in the 1st Battalion Gordon Highlanders, and had received a bullet wound just below the left knee on April 3rd, 1895, at the battle of Malakand Pass, Chitral Expedition. He was admitted to hospital and the wound explored, and he stated that three pieces of lead were removed, although this statement was not supported by documentary evidence. The wound eventually healed up, and the man was sent home and admitted to Netley Hospital on April 28th, 1895. On his admission there he had a firmly cicatrised wound two and a half inches in length situated just below the level of the tubercle of the left tibia on the inner side of the leg. The bone was not enlarged, and pressure on the cicatrix was not painful. He complained, however, of pain deep in the bone at times and lameness, and he fancied that the bullet or some part of it remained in the bone. With the assistance of Surgeon-Captain Aldridge skiagraphs were taken of the leg in two positions—the first from the anterior aspect and the second from the inner surface. A spherical bullet was at the same time fastened against the limb, in order that its image might appear in the picture and might assist in determining whether a bullet was embedded in the bone or not. Both skiagraphs showed a disc of metal, the conclusion, therefore, being that the bullet was present

Hosted by Google

and was spherical in shape. Having taken the measurements carefully so as to locate the exact position of the bullet, Surgeon-Major Whitehead cut down, and by trephine, gouge, and chisel penetrated the bone to the depth indicated. The bullet, however, was not immediately found; the surrounding bone was therefore prospected by a drill till a hard substance was felt slightly below the original cavity. On clearing the bone away and applying the electric bullet-explorer it at once indicated the presence of the bullet. On illuminating the cavity by a small electric lamp the bullet could be seen firmly embedded in the substance of the bone, and it was removed without further difficulty.

Remarks by Surgeon-Major WHITEHEAD.—The interest in this case centres in the help derived from the Roentgen rays. There was nothing objective to make one believe that the bullet was still present. The subjective symptoms, however, pointed to this as a possibility. We doubt if any surgeon would have cared to prospect to the depth at which the bullet was at length found unless he had strong evidence of its presence. By means of the skiagraph obtained by the Roentgen rays all doubt was placed at rest, and the operation was confidently undertaken.

STRATFORD-ON-AVON HOSPITAL.

A CASE OF INTESTINAL OBSTRUCTION DUE TO BANDS; ONE DIVIDED BY OPERATION; OTHERS FOUND POST MORTEM.

(Under the care of Mr. HARRY LUPTON.)

STRANGULATION by a "band" is by no means an uncommon cause of intestinal obstruction, and in the vast majority of cases only one band is present; in fact, so rare is it to meet with more than one that Gay described them under the name of "solitary bands." They are, however, by no means always solitary, but may be very numerous, and, indeed, it seems strange that they are not more frequently multiple when it is considered that their formation is due to peritonitis. The treatment to be adopted in any case of intestinal obstruction must depend greatly on the patient's general condition. If this be bad, the less the bowel is manipulated the better; but if, on the other hand, the patient's general condition is good it is certainly advisable to examine systematically the whole of the intestine in order to see if more than one obstruction exist.

A man, aged twenty-one years, was admitted into the Stratford-on-Avon Hospital on Sept. 19th, 1896, with a history pointing to intestinal obstruction. He was thin and looked phthisical, with flattened sub-clavicular regions. He had waxy, transparent-looking hands, a pinched aspect, with sunken eyes; the temperature was sub-normal, the pulse was fast and inclined to be running; the extremities were cold, and the patient was suffering generally from his journey to the hospital. There was a history of bowel trouble for the previous seven days. During the last three days he had had no passage of fæces save a small amount brought away by enema, and this period was also one of vomiting. He had been sick last on the morning of admission. The practitioner who had seen him outside then sent him into the hospital with a view to operative interference. When the patient had somewhat rallied he was seen in consultation, when it was decided to try the effects of a copious enema before proceeding to other measures, if such were found necessary. It should be noted that his abdomen was pinched and flat, showing no signs of distension, and that his inguinal rings were clear, and no tumour was to be felt in the right flank or elsewhere. The enema brought away, with smaller fragments, four large, hard masses, somewhat larger than a pigeon's egg, brown, slime-coated, and evidently old inhabitants. It seemed probable that these masses might have been the cause of the obstruction—they might be said to have been "facetted," and as if they had dove-tailed into one another—and their removal gave so much relief that a "rest-and-be-thankful" policy was adopted, which policy appeared to be fully justified for twenty-four hours, when a dose of castor-oil was ordered. This was rejected before it passed the mouth, and was followed by vomited matter distinctly feculent in its character. Thereupon, after a further consultation, it was decided that the abdomen should be opened, and the cause of the obstruction sought for. This was accordingly done forthwith, Mr. Norbury and Mr. Greene rendering valued assistance, and chloroform being administered by Dr. George Clark Stewart. The abdomen was opened in the middle line. A couple of fingers swept round the pelvis proved the absence of any hernia at the usual sites, nor could any abnormality be detected in the region of the ileo-cæcal valve. The incision was then prolonged upwards, nearly to the umbilicus. Almost immediately beneath it a coil of congested intestine was seen; this proved to be bound down by a band of about the thickness of a porcupine quill. The intestine appeared to be collapsed on one side and distended on the other. No minute investigations as to the relations of the band were made. It was divided between two pairs of pressure forceps. At this juncture the patient vomited violently and became very collapsed; the intestine, immediately released, swelled up, and the pulse improved. Rapidly passing the fingers over and amongst the intestines disclosed no other obstruction, and Mr. Lupton concluded that he had removed the cause of trouble, and was, moreover, anxious to complete the operation and have the patient in bed again as soon as possible. A sponge passed into the pelvis not returning dry it was decided to drain the pelvis—at all events, for the first twelve hours. The abdomen was cleansed by sponging, and the wound closed with interrupted sutures. On the whole the patient was in a somewhat better condition when removed from the table than when placed upon it, but still bad enough, and a subcutaneous injection of ether was given before he was removed to the ward. On the following morning (sixteen hours after the operation) the patient seemed to be better and expressed himself as relieved. About two ounces of clot and serum had been withdrawn from the drainage-tube—during the last two hours only a couple of drachms of clear, sweet smelling serum. The drainage-tube was removed, and an additional suture tied at the lower end of the wound. All went well till the afternoon, when symptoms of collapse came on, with further vomiting, and he died about twenty-four hours after the operation.

Necropsy.—Permission was obtained to make a post-mortem examination, which was done twenty-four hours after death. The abdomen was opened slightly to the right of the middle line, the insertions of the recti were divided, and the abdominal wall turned back, so as to show the inner aspect of the incision. This was well united, the omentum being adherent along the line of incision. There were no signs of peritonitis and no fluid in the pelvis. On following the intestine down from the duodenum another band was met with, less than the one which had been divided at the operation; it gave way when the finger was placed under it. Further down in the ileum was yet another, passing across the bowel and completely constricting it. And yet nearer to the ileo-cæcal valve the ileum made a journey across to the left brim of the pelvis, where it was crossed by a band passing from the brim of the pelvis to a point below the sacral promontory. This also constricted the bowel, and it was easy to see that the operator's fingers had passed *above* this at the time of the operation and so failed in detecting it. It was barely clear of the pelvic brim until lifted by the fingers.

Remarks by Mr. LUPTON.—That a man should have had four distinct obstructions to a free passage through his intestines, all caused by abnormal and separate adventitious bands, is, I think, unusual. The fact that the operation I undertook for the man's relief failed by reason of its insufficiency I must sorrowfully admit, but the point remains, Did I leave undone at the time of the operation, and under the circumstances, what I ought to have done? It is easy to be wise after the event, and it is far easier to detect abnormal conditions on the table of the post-mortem room with an incision extending from the xiphoid cartilage to the pubes and the insertions of the recti divided, and when there is no fear of collapse before our eyes, than it is in the operating-room, with a limited incision and with a patient in parlous condition on the table. Had I turned out through the limited incision and overhauled the whole length of the intestines I should, no doubt, have found the remaining obstructions. But, to put a perfectly imaginable case, suppose I had done this and found no other obstruction, and the patient failed to rally after the operation, I should naturally have thought, How very unwise I was not to be satisfied when I had released the obvious constriction and how much I wish I had left the rest of the intestines alone. The point appears to me to be interesting, and I would venture

Hosted by Google

a hope that some whose experience of abdominal surgery is greater than my own may discuss it. In operating for intestinal obstruction, is it advisable to be content when an obstruction has been found and removed, or should it be the rule to overhaul the whole length of the intestine? My own feeling is that cases of multiple obstruction must be so rare that when an obstruction is found and freed, the sooner the wound is closed and the less the disturbance of the remaining intestine the better. I am inclined to think that had I another case with a similar history I should be content with having found an obstruction and released the confined bowel. The bands referred to, with the exception of the pelvic one, passed once across the bowel, from attachment to attachment. It was not the case that a knuckle of intestine had slipped under either one of them, though it was so in the pelvis. I shall be glad if the narration of this case leads to authoritative expression of opinion.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Non-Tuberculous Posterior Basic Meningitis.

A MEETING of this society was held on April 27th, Dr. WILLIAM MARCET, F.R.S., Vice-President, being in the chair.

The adjourned discussion on the paper by Dr. J. W. Carr, read at the meeting of the society on April 13th, and reported in THE LANCET of April 17th, was opened by

Dr. BARLOW, who congratulated Dr. Carr on the thorough and clear presentation of the group of cases referred to in his paper. It was very satisfactory to him to find that Dr. Carr confirmed the description of the clinical type given by him and Dr. Gee years ago. The most typical symptoms were: (1) opisthotonos, which dominated the clinical picture and was a constant, early, and aggressive feature; (2) vomiting; and (3) the tendency to the occurrence of tonic spasm, different from the clonic spasm and subsequent paresis which occurred in tuberculous meningitis as a result of cortical irritation. The limbs were almost always rigid in an extended position. The essential anatomical feature was the occurrence of meningitis, with its maximum in the posterior fossa. Both the intensity of the inflammation and the amount of its extension anteriorly to the base of the cerebrum or downwards into the spinal canal were very variable. But whatever the intensity or extent of the inflammation, it was always characterised by the tendency to the formation of cicatricial adhesions. These could be found post mortem at various points along the spinal cord and often at the tip of the temporo-sphenoidal lobe. But they were particularly apt to occur in the roof of the fourth ventricle, blocking the foramina there. This was accurately described by Hilton in his work on "Rest and Pain," but was only one of the causes of hydrocephalus, as this condition might be produced when the foramen of Magendie was patent. He had seen one case in which it was produced through the blocking of the foramen of Monro, others in which the aqueduct of Sylvius was closed, and one in which the anterior part of the roof of the fourth ventricle was adherent to its floor, and he thought that obstruction sometimes occurred from complete adhesion of the spinal meninges at the level of the first and second cervical vertebræ. With regard to the etiology, he agreed that syphilis was not an operative factor. Syphilitic meningitis did occur, but was usually associated with gummata, signs of cirrhosis, and vascular changes. In one case where symptoms like those described in the paper came on they followed a blow on the occiput, and there were signs of traumatism in the dura mater. Unlike the cases of purulent meningitis that usually followed an acute disease, such as broncho-pneumonia, empyema, &c., and which had a more fulminating character, the posterior basic cases came on in previously healthy infants. But both Dr. Lees and himself had been struck with the frequency with which a history of some catarrh had been met with just before the onset of acute symptoms. It was well known that in infants catarrh of any organ tended to become generalised. He thought that some part was possibly played by the moderate amount of otitis media which was found post mortem in these cases as well as in the bodies of most infants dying from disease. It was conceivable that the muco-pus in the middle-ear formed a convenient nidus for the development of organisms which passed from the fauces along the short Eustachian tubes of an infant. The period of life when posterior meningitis was most frequently met with coincided with that during which there was the greatest tendency to middle-ear disease. Many of the cases came from insanitary houses. With regard to treatment the possible causative effect of catarrh and of otitis media must be remembered. In eight cases in which the symptoms appeared to indicate the commencement of posterior meningitis the symptoms were at once relieved by puncture of the tympanic membranes. A certain number of cases had recovered under mercurial treatment. At his suggestion Mr. Ballance had devised an operation for tapping the fourth ventricle, and the symptoms had been relieved for a time, but never permanently. In one case in which a little fluid only was obtained from this region paracentesis of the ventricles through the fontanelle was also practised, and the patient left the hospital well. He died some weeks later, and at the necropsy the signs of meningitis had quite subsided. This case was operated on early and probably that conduced to the good result obtained. In the cases that recovered there was often amaurosis, apparently complete, without any ophthalmoscopic change.

Dr. LEES referred to a case which he had published some years ago in which life was saved by paracentesis of the tympanic membranes. Basic meningitis was mainly a disease of infants under one year of age, but might occur later. He was unable to accept Dr. Carr's explanation of the source of the fluid as due to obstruction of the ventricular veins. He thought that their engorgement was either part of the inflammatory process or secondary to the distension of the ventricles. The low specific gravity and the small amount of albumin present proved that the fluid was neither inflammatory nor dropsical in origin. The fluid, he believed, was cerebro-spinal fluid, and its accumulation was due to some obstruction in the channels which led from the ventricles where the fluid was secreted by the choroid plexuses to the sub-arachnoid space, from which, as Key and Retzius had shown, it was drained off by the roots of the cerebral and spinal nerves. He observed that Dr. Carr found the foramen of Magendie closed in half of his cases, and in two more it was not excluded. He insisted on the importance of examining the condition of this foramen *in situ* before the rest of the body was opened by removing the occiput and the laminæ of the upper cervical vertebræ and then opening the dura mater. The foramen was large proportionally in infants. Closure of the channel might also occur at other points, as described by Dr. Barlow. He confirmed the statement that optic neuritis was very rare, although both increased intra-cranial pressure and meningitis, which were supposed by many to be the efficient factors, were present. Nystagmus was common, and he believed it to be due to cerebellar influence. The patients were often blind, even when hearing appeared to be acute. Slowing of the pulse was less frequent than in tuberculous meningitis, possibly because, owing to the age of the patients, the inhibitory power of the vagus was not developed. The opisthotonos was often extreme, the occiput nearly touching the buttock. The lower limbs were usually in a state of extensor spasm, and the upper limbs were as rigid as the lower, and also usually extended, but occasionally flexed. If the limbs were watched a periodical accentuation of the spasm might be observed, which he attributed to the influence of the cerebellum. The rhythm of the respiration was rarely typical Cheyne-Stokes, but what he called "cyclical," there being a pause followed by three or four deep, sighing respirations. The amaurosis described by Dr. Barlow completely passed off in some cases.

Dr. NORMAN MOORE mentioned that it was the study of a case of tuberculous meningitis which led Monro to the discovery of the foramen that bears his name. He doubted whether one pathological explanation would be found to cover all the cases, and asked whether some of the cases could be possibly rheumatic in origin. He remarked that the opisthotonos often diminished for a few days before death.

Dr. CHURCH said that from the cases that he had seen he was inclined to take a more hopeful view of the prognosis. Two of the most severe cases had recovered completely at the time that they left hospital. In one of these the opisthotonos was so great that at one time the occiput was only three inches from the buttock. Both patients when they had

Hosted by Google

recovered from the meningitis were found to be blind, although there were no ophthalmoscopic changes.

Mr. BALLANCE said that the first case that he had operated on at the Great Ormond street Children's Hospital was in 1891, and the operation had also been performed independently by Mr. Parkin of Hull and others. He operated by turning down a U-shaped flap and then making a small opening with a trephine on one side (or, better, on both sides) of the middle line in the occipital region. In consequence of the extreme retraction of the head it was convenient to use a special trephine with a long handle. The symptoms were in almost all cases temporarily relieved. He thought that the peculiar "chewing" or "champing" movements of the lower jaw were probably cerebellar, as they were met with in cases of abscess and tumour of that organ. The most effective treatment in the cases that he had seen, other than operation, was administration of mercury internally and incision of the tympanic membranes. He believed that if the disease were of an infective nature early operation would have most influence in stopping it. He had recently seen a case with Dr. Buzzard in which purulent infection of the ventricles came on in an adult after the evacuation of an abscess in the cerebellum. Bacteriological investigation by Dr. Jeffner showed that Fränkel's pneumococcus was present, and the injection of a suitable antitoxin serum supplied by Dr. Washbourn relieved the symptoms. Probably if the organism present in these cases could be discovered treatment on these lines would be successful.

Mr. RAYMOND JOHNSON said that he had operated on two of the cases detailed by Dr. Carr, but he should not be inclined to operate again if there was already hydrocephalus, as when free exit was given to the fluid the skull collapsed, and death occurred a few hours later. He thought that early operation alone could be of benefit.

Dr. JOHN ABERCROMBIE said that there seemed to be a season for these cases, most of those he had seen occurring in the spring. One year he saw several in which the symptoms first appeared on the same day in March, and in one instance two children were attacked in the same family. The youngest case that he had seen was that of a child six weeks old, and the disease then ran a very rapid course, death occurring in three weeks.

Dr. CARR, in reply, said that after the information given by Dr. Lees and Dr. Barlow, he felt that the dropsical theory would not account for the effusion of fluid, and he adopted their view that it was retained cerebro-spinal fluid. There was no evidence of a rheumatic causation in any of his cases.

MEDICAL SOCIETY OF LONDON.

Senile Tuberculosis.—Treatment of Gout by an Exclusive Meat Diet and Hot Water.

A MEETING of this society was held on April 26th, the President, Mr. REGINALD HARRISON, being in the chair.

Mr. HOWARD MARSH read a paper on Senile Tuberculosis, which will appear in our columns in full.—Mr. ARMSTRONG spoke of the difficulty of diagnosing between osteo-arthritis and tuberculous disease of the joints in the early stage, and described a case in point in which the diagnosis was only clearly made when softening and suppuration occurred.—Dr. COLMAN referred to three cases of tuberculous disease of the vertebræ in patients sixty years of age without curvature, where the nature of the affection was proved by post-mortem examination, and he confirmed the statement that in adult cases there was often no curvature. He had seen angular curvature produced by syphilitic pachymeningitis, and recalled one case of extensive erosion of vertebræ by an aneurysm in which case there was no curvature, the articular processes being greatly thickened.—Dr. HILL also mentioned a case in which a psoas abscess and an aneurysm eroding several vertebræ were present in the same case without there being any curvature.—Mr. G. R. TURNER referred to the great difficulty of diagnosing between tubercle and syphilis in these cases. In one case the appearance at first pointed to tubercle, and this was confirmed by the presence of signs of tuberculous lung trouble, but the course of the case proved that it was syphilitic.—Dr. THOROWGOOD asked if tubercle bacilli had been found in these cases. He was at present treating an old man suffering from tuberculous laryngitis and phthisis, who had developed an inflammatory affection of the subcutaneous tissues of the back of the hand, which he thought would prove to be tuberculous.—Mr. HOWARD MARSH, in reply, said that bacilli had been found in many of the cases, but that it was often a matter of difficulty to find them even in advanced cases where the diagnosis was not in question. The difficulty of distinguishing between tubercle and syphilis was increased by the fact that they were often present in the same case.

Mr. WILLIAM ARMSTRONG read a paper on the Salisbury Treatment of Gout, which will shortly appear in our columns.—Dr. A. HAIG said that he was familiar with the improvement often noticed in cases treated in this manner, at any rate for a time. It was as difficult at first sight to explain the improvement in cases of arthritis as to explain the good effects of a course of mineral waters at spas where the waters contained abundance of sulphates and lime salts. The same explanation would probably apply to both. He thought that both were stimulants, and as such their first effect was to eliminate uric acid. Meat not merely clears the blood of uric acid, but introduces it into the blood, or at least its physiological equivalents, hypoxanthin, &c. He quoted several cases to show that the treatment is by no means without danger, and he attributed the untoward symptoms to the accumulation of uric acid.—Dr. LUFF said that the effect of the mineral salts in the meat must not be lost sight of. In his recent experiments he had found that the presence of these salts had a great effect in inhibiting the maturation of the ordinary sodium biurate into the quadriurate, which he regarded as one of the chief causes of gout. He did not believe that uric acid was a normal constituent of the blood in man or other animals. It was present in gout from absorption from the kidney, the organ in which it was mainly formed and excreted. Uric acid was also present in the blood in leucocythæmia and pernicious anæmia, and was apparently derived from destruction of the white corpuscles.—Mr. BUCKSTON BROWNE said that no doubt the treatment was very successful in certain cases for a time, but it could not be persevered with for long without danger. He was inclined to attribute the good results obtained to abstention from sweets and starchy food and alcohol rather than to any virtues in the meat diet. He preferred to give a little starch, and all vegetables that grow above ground as well as potatoes and onions, and a moderate meat diet. Under careful diet on these lines symptoms due to uric acid rapidly disappeared.—Dr. THOROWGOOD asked as to the previous habits of the patients who had benefited by the treatment. Persons who lived much on farinaceous food were very liable to flatulent dyspepsia, and their symptoms were often attributed to gout, but rapidly disappeared when the diet was corrected. Possibly uric acid was actually formed in the stomach.—The discussion was adjourned to May 10th.

CLINICAL SOCIETY OF LONDON.

Myeloid Sarcoma of the Jaw.—Congenital Dislocation of the Shoulder.—Hydro-nephrosis.—Muscular Dystrophy.—Subclavian Bruit without any other Symptoms.—Myositis.—Dwarfing of Humeri.—Symmetrical Orbital Swellings.—Keratosis.

A MEETING of this society was held on April 23rd, the President, Dr. BUZZARD, being in the chair.

Mr. CHARTERS SYMONDS showed a boy, fifteen years of age, from whose Lower Jaw he had removed a central Myeloid Sarcoma fifteen months before. The tumour had destroyed a large portion of the jaw and not only projected in front but passed backwards under the tongue. It was removed by enucleation and free erasion from the bone, a bridge of bone along the alveolar border being all that was left for some distance on each side of the middle line. There had been no recurrence, and the patient had now a firm, bony jaw and practically no deformity.

Mr. F. S. EVE showed a case of Congenital Dislocation of the Shoulder. The patient was an infant, nine months old, who was delivered with forceps after a lingering labour. The head of the humerus was displaced backwards, lying just below the spine of the scapula. The case was similar to one shown by him to the society some years ago, in which he had operated and had found the joint well developed, the head of the bone being elongated obliquely backwards. He had to shorten this by shaving off the redundant cartilage

Hosted by Google

before he was able to put the bone into a proper position; the ultimate result was satisfactory. He thought that the condition was usually due to injury during birth through undue traction on the axilla or to careless handling by the nurse after birth. In one case there was definite evidence of stretching of the brachial plexus.

Mr. HOWARD MARSH showed a case of Hydro-nephrosis in which the collection of fluid was found between the kidney and the capsule. The patient was a man, twenty-one years of age, who was admitted to St. Batholomew's Hospital on April 23rd, 1896, with the history that he had had uneasiness in the left lumbar region for some years, and that three weeks before he had been seized with intense pain in this region which had persisted. The man appeared very ill, and on examination a large, tense, fluctuating tumour was felt. This was incised through the loin and a large collection of blood-stained fluid was found between the capsule and the kidney, which was found collapsed at the bottom of the sac and was removed. Mr. Marsh thought that the hydro-nephrosis must have occurred very rapidly, and the fluid must have been forced through the substance of the kidney, stripping off the capsule. The cyst was drained, but closed very slowly, and even now there was some slight escape of fluid from the wound every few weeks. The patient had completely recovered his health and had resumed his work. Nothing had been discovered to indicate the cause of the hydro-nephrosis.—Mr. G. H. MAKINS said that he had seen Sir William Mac Cormac operate on a case in which a similar collection of fluid between the organ and its capsule occurred as a sequel to traumatic rupture of the kidney.

Dr. W. ESSEX WYNTER showed a case of Muscular Dystrophy of the Landouzy-Déjerine type in a lad, ten years of age, who was admitted to the Middlesex Hospital in January, 1897, on account of a gradually increasing feeling of fatigue and progressive difficulty in walking. As an infant he was backward and did not cut his first tooth till he was four years old. He now exhibited almost complete paralysis of the facial muscles; the muscles of the upper and lower limbs were weak and wasted and showed diminished electrical excitability. The muscles round the right shoulder were most affected, the deltoid having almost disappeared. None of the other members of the family were affected.

Mr. CHARTERS SYMONDS showed a man, twenty-five years of age, with a loud Subclavian Bruit. He had been under observation for six years and during that time he had had prominence and pulsation beneath the left clavicle, and a loud bruit was to be heard in this position. The left pulse was somewhat weaker than the right. As no change had taken place during this time it was clearly not an aneursym, and Mr. Symonds thought that it was most likely due to the presence of a supernumerary rib which was pressing the subclavian artery forward. He had met with two other cases of subclavian bruit without symptoms—one in a healthy athletic young man, in whom the cause was not known, and the other was probably due to traction on the subclavian artery by the shrinking of the apex of the left lung in a patient with advanced phthisis.—Mr. CLEMENT LUCAS remarked that the late Mr. Hulke had published several cases of this kind, which were at first thought to be exostosis of the first rib, but which were afterwards admitted to be due to a supernumerary rib, and he agreed that this was the probable explanation in this case.—Dr. KINGSTON FOWLER said that the presence of a bruit, or even of a thrill, was not enough to justify the diagnosis of organic disease of the vessels, and he pointed out that in some persons a bruit could be produced merely by pressing the shoulders back.—Dr. C. W. CHAPMAN alluded to the case of a lad, eighteen years of age, who had pulsation and thrill over both subclavian arteries. There was at one time pain down both arms, but this ultimately passed off, although the thrill and bruit persisted.

Dr. KINGSTON FOWLER showed a case of Myositis in a man fifty-four years of age. The patient had previously enjoyed good health and had never had syphilis or gout. In January, 1895, his left thigh became painful, and after a short time some of the muscles were found to be swollen. This swelling increased for some days, the muscles being very hard without œdema of the surrounding parts. There was then a period during which the swelling remained stationary, and it afterwards slowly and completely disappeared. Subsequently various muscles in the calf, shoulder, and other parts were in turn affected in an exactly similar manner, the swelling ultimately completely clearing up except in the biceps, where there were now two small firm nodules. Hard subcutaneous swellings had also formed in the abdominal walls and slowly cleared up, leaving knotty indurations. At present the muscles of the left arm were passing through an attack, the axillary glands were enlarged, and there was some induration of the skin of the neck similar to that formerly present in the abdominal walls. Skiagrams of the arm showed that the bones were normal and that there were no actual bony deposits in the muscles. Dr. Fowler raised the question whether this case ought to be placed in a separate category from myositis ossificans, and suggested that possibly ossification did not occur owing to the patient's age. Warm baths had given the man more relief than any other mode of treatment.—Mr. CHARTERS SYMONDS said that this patient had formerly been under his care at Guy's Hospital, and he confirmed the description of the cycle of changes in the muscles given by Dr. Fowler. Anti-syphilitic remedies had been thoroughly tried without the slightest benefit.—Dr. PARKES WEBER said that the case was like those which had been described as "relapsing dermato-myositis." In several of the recorded cases there had been affection of the glands and nerves. From the position of the patient's hand in this case (Charcot's "attitude of benediction") there must be some paralysis of the ulnar nerve, and the case might therefore, perhaps, be described as one of neuro-dermato-myositis.

Mr. F. S. EVE showed a girl, fourteen years of age, with marked Dwarfing of both Humeri. The condition was first noticed on the right side when she was six years old, and the left limb was affected shortly afterwards. The humerus was now three inches, and the arm as a whole four and a half inches, shorter than the standard for a girl of her height. The lower limbs were normal. There were some creaking and limitation of movement in the right shoulder and a little also in the left. The girl was fat, somewhat lethargic, and she was slow at her lessons. The thyroid gland was not palpable. She was the youngest of eleven children, the others being healthy. There was no direct evidence of specific disease, but there was slight scarring at the angles of the mouth. He thought that the diagnosis lay between a cretinoid condition and syphilitic epiphysitis of the upper ends of the humeri. This would account for the changes in the shoulder-joint.

Dr. W. ESSEX WYNTER showed a boy, aged five years, who exhibited Symmetrical Swellings in the Orbits and both Temporal Regions. He was under the care of Mr. Treacher Collins in 1896 for proptosis of the left eye with failure of vision. Optic neuritis was present and was followed by atrophy. An exploratory incision was made into the orbit, but without disclosing the cause of the swelling, which afterwards subsided. Some months later swelling occurred in both temporal regions, the right eye became prominent, and the sight began to fail, and when admitted into the Middlesex Hospital he had optic neuritis. The parents thought that there had been some impairment of intelligence and difficulty in walking during the last month. There was some enlargement of the glands in the axilla, neck, and groins, and one of these, which was excised, proved to be tuberculous. Round the margin of the swelling in the right temple there were some hard nodules, apparently bony elevations on the cranium.

Dr. COLCOTT FOX showed a lad, ten years of age, who exhibited extreme Keratosis of the nail beds, causing deformities of the fingers and toes, as well as perfectly symmetrical Horny Callosities of the size of walnuts over the ankles, with smaller ones, also symmetrical, on the soles, popliteal spaces, and buttocks. Dr. Fox pointed out that pressure could not account for many of them. The father and grandfather were said to have had a similar condition of the nails and to have had remarkably coarse hair, but there was nothing unusual in the patient in this respect. Dr. Fox showed illustrations from other recorded cases of the kind.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Sewer Ventilation and Health.

A MEETING of this society was held on April 9th, the President, Dr. G. P. BATE, being in the chair.

Dr. F. J. ALLAN read a paper on Sewer Ventilation and Health, the outcome of inquiries conducted by himself at the

Hosted by Google

request of the Strand Local Board as to the experience of a number of sanitary authorities in London and elsewhere with regard to street sewer ventilators. With one or two exceptions the replies, fifty-eight in number, admitted the fact of complaints of offensive smells—at least, in some parts—but the answers to the question whether they had been able to trace any deleterious influence on health to emanations from the street level or other ventilators were less definite, save as regards shafts, to which, when not most improperly placed, no objections were raised, and some authorities found their action, alone or in association with openings at the street level, perfect, the lower apertures where they were retained being converted into inlets only. Notwithstanding the negative evidence as to the occurrence of disease germs in sewer air or gases, Dr. Allan maintained that its inhalation could not but be hurtful by inducing a low state of health, diminished resistance to infection, and, as Alessi's experiments showed, a condition highly favourable to the growth of pathogenic organisms, especially those of a septic character. The poison was, he thought, not so much in the well-known hydrocarbons and sulphur compounds as in indetermined organic products like those given off from the lungs, most abundant and most virulent in ill-constructed sewers, with foul deposits, and in those receiving hot water and factory wastes. That such gases must be allowed to escape, and that their entrance into houses, either directly or by forcing of traps, must be prevented, was obvious; but he doubted the soundness of the views of those who advocated unlimited dilution of sewer air by multiplication of openings as involving a corresponding contamination of the atmosphere of our towns and logically justifying the return to open gutters in the street. He admitted the necessity for ventilation so far as to relieve the pressure on the traps, but held that it should not be more than was required to compensate for the movements of the sewage and changes of atmospheric pressure and temperature, while every effort should be made in the way of improved construction and flushing to avoid deposits and putrefaction. After referring to contrivances in his own district for a coarse screening of the out-going air, and at Worcester for its filtration through cotton-wool treated with germicides, as well as to the Reeves system of chemically evolving permanganic acid and sulphurous dioxide in the ventilating shafts, he went on to discuss the replies he had received as to the practical working of the Keeling-Holman and Webb's or Deakin's patents for ventilating and burning the sewer gases; those as to Keeling's, in which the combustion was effected in a gas furnace in the base of a column, were on the whole unsatisfactory on the score either of efficiency or of cost; but they were decidedly favourable as to Deakin's, in which the sewer gases were burnt in the lantern with apparent increase of illuminating power. Dr. Allan's conclusions were that well-constructed sewers required compensatory ventilation only, which might be at any level, whereas in those of a different character some form of constant ventilation was necessary, the outlets being preferably at a considerable elevation, and that the best arrangements were those providing for the combustion of the gases at the same time.

LIVERPOOL MEDICAL INSTITUTION.

Malignant Growth of the Orbit.—Tumour of the Pons Cerebri.—Presystolic Murmur without Mitral Stenosis.—Addison's Disease.—Peroneal Spasm.

A MEETING of this society was held on April 22nd, 1897, Mr. CHARLES SHEARS, Vice-President, being in the chair.

Mr. C. G. LEE showed a case of Malignant Growth of the Orbit. The patient was a man, aged forty-three years, who had, in October, 1895, a swelling at the inner angle of the right orbit. The growth was considered to be a sarcoma both by Mr. Lee and Mr. Edgar Browne. An operation was performed at once. The growth extended deeply into the orbit above and downwards into the antrum; only a portion of the growth was removed. The patient made a slow recovery, but by January, 1896, the growth had again made its appearance; it was now on a level with the superciliary ridge, and was slightly depressing the eyeball outwards. The tumour continued to grow until March, 1896, when the patient was lost sight of. However, in the following October he again presented himself, when there was scarcely any sign of tumour. The patient attributed his improvement to the use of Ceylon cinnamon. Sections of the excised portions of the tumour were pronounced to be of a malignant nature.—Mr. LARKIN described a case he saw several times with his colleague, Dr. Grossmann, and which closely resembled Mr. Lee's case. The patient also recovered, but without using cinnamon.—Mr. SHEARS also made remarks.

Dr. P. DAVIDSON read notes of a case of Tumour of the Pons Cerebri. The rapid occurrence of paralysis of the sixth and seventh cranial nerves of the right side, with weakness and ataxia of the lower limbs and increased knee-jerks, warranted the diagnosis of a tumour invading the right side of the pons. The subsequent occurrence of paralysis of the left sixth and seventh cranial nerves confirmed the diagnosis of a rapidly growing mass. The diagnosis was entirely confirmed by the necropsy, the tumour being tuberculous. No optic neuritis was present during the first two months.—Mr. RICHARD WILLIAMS said that all the cases of cerebral tumour he had seen had optic neuritis sooner or later, but naturally only the cases whose vision was affected were likely to come under his observation.—Mr. BICKERTON said that in many cases of cerebral tumour optic neuritis did not occur.—Mr. MACLEOD ROSS, Mr. SHEARS, and Mr. C. G. LEE also discussed the point as to the frequency of cerebral tumour without optic neuritis.

Dr. A. DAVIDSON drew attention to the occasional occurrence of a Presystolic Murmur at the Apex of the Heart in cases of Aortic Regurgitation, where subsequent post-mortem examination showed the absence of mitral stenosis. He referred to two cases where this occurred in his own hospital practice. The same observation had been made by the late Dr. A. Flint of New York, and the matter was referred to at length by Dr. Sansom in his book on the heart, otherwise it appeared to be much overlooked.—Mr. MACLEOD ROSS suggested that in some cases of aortic regurgitation where there was no mitral stenosis yet a presystolic murmur, it might be the result of digitalis or other cardiac tonic.—Dr. O'HAGAN related a case which had been examined by men of the highest standing. This patient had a presystolic murmur, but at the necropsy there was no mitral stenosis.—Dr. A. C. E. HARRIS thought the characteristics of a presystolic murmur were mainly its roughness and limited diffusibility, and that in the cases in question these characteristics would be lost or the murmur might be of a musical kind. The importance of Dr. Davidson's observations on prognosis he fully realised.—Dr. DICKINSON, Dr. BRADSHAW, and Dr. BUCHANAN took part in the discussion.

Dr. BRADSHAW read a note on Addison's Disease. He pointed out that neither the glandular nor the nervous hypothesis of the pathology of the disease was quite satisfactory. He criticised Mühlmann's hypothesis, which is that the adrenals are concerned with the elimination of pyrocatechin, which they effect under the influence of the sympathetic, and that when the adrenals or the sympathetic are diseased pyrocatechin accumulates in the blood, and by its toxic action gives rise to the symptoms of Addison's disease. Dr. Bradshaw showed that when pyrocatechin was in the blood it quickly appeared in the urine, but he had failed to find evidence of it in the urine of three patients with Addison's disease who had been under his care during the last few weeks. This and other considerations led him to conclude that Mühlmann's idea could not be maintained. He then showed two patients with Addison's Disease, and the Caseous Adrenals of a patient whom he had shown previously to the society. The semilunar ganglia appeared normal.—Dr. STOOKES and Mr. NEWBOLT made remarks.

Mr. ROBERT JONES read a note on Peroneal Spasm and its Treatment. He drew attention to the causal relationship of spasm of the peronei to a certain type of flat-foot. Many flat feet were accompanied by spasm, but in one variety exhibiting characteristic symptoms the spasm proved the sole cause of the deformity. Of sixty tabulated cases males were affected in the proportion of four to one. Mr. Jones dwelt on the differential diagnosis of this condition from osseous, rheumatic, and hysterical valgus. He had operated on forty cases and found nothing short of an excision of portions of the peronei sufficed. An incision was made at the side of the fibula just above the malleolus, and the peroneus longus was laid bare and about three-quarters of an inch removed. The peroneus brevis was exposed and the same amount of its tendinous portion excised. The foot was then placed in a

Hosted by Google

varus position for a fortnight and the patient allowed to walk with an altered boot in three weeks. Simple tenotomy was not sufficient.—Mr. NEWBOLT had seen a number of cases of spasmodic flat-foot, and he agreed with the method of treatment adopted by Mr. Jones.—Mr. PUZEY and Mr. MURRAY made remarks.—Mr. JONES replied.

PATHOLOGICAL SOCIETY OF MANCHESTER.

Nerve Cells.—Exfoliating Cystitis.—Recurrent Appendicitis.—Pernicious Anæmia.—Exhibition of Specimens.

A MEETING of this society was held on April 14th, Dr. THOMAS HARRIS, the President, being in the chair.

Mr. FRICKE gave a Lantern Demonstration on the Structure of Nerve Cells, and discussed some recent methods of investigation.

Dr. WALLS described two cases of Exfoliating Cystitis secondary to retroversion of the gravid uterus. The first patient came under treatment when four months pregnant, and although the conditions were so bad that a fortnight elapsed before the uterus could be replaced pregnancy went on to term. The second patient presented herself after abortion had taken place.

Mr. SOUTHAM made some remarks on the Pathology of Recurrent Appendicitis, and exhibited a number of appendices removed from twenty cases treated by operation. These showed the changes usually met with in this condition—viz., thickening of the wall of the appendix, with constriction or occlusion of its lumen, which in many cases was dilated on the distal side of the obstruction and distended with fluid. In three cases fæcal concretions were found and in one instance a pin. Suppuration had occurred in eight instances, a localised abscess having formed in six cases, while in two there was diffuse purulent peritonitis. Specimens were also shown to illustrate the fact that adhesions might be present after a single attack, or absent after many attacks, of appendicitis.

Dr. MERCER showed Preparations from a case of Pernicious Anæmia in a child aged seven years, running a rapidly fatal course and marked by profound anæmia with pyrexia and gastro-intestinal disturbances. The red blood corpuscles were reduced to 1,000,000 per cubic millimetre and the hæmoglobin to less than 20 per cent., with marked poikilocytosis. The chief points of interest were: (1) the age, the disease being distinctly rare in children; (2) the rapid course the duration from onset to death being less than three months; and (3) the probability of the disease being of septic origin. The child had long-standing middle-ear mischief, and the rapid course and symptoms generally pointed to a rapid destruction of the red corpuscles by the action of a toxin in the blood. At the post-mortem examination advanced fatty degenerative changes were found in the liver and heart, together with a small amount of deposit of iron granules in the liver cells. The spleen was somewhat enlarged, but no morbid changes were discovered under the microscope. The red marrow contained numerous nucleated red corpuscles, but no other abnormal cells.

The following card specimens were shown:—

Dr. FOTHERGILL: Chorioma Malignum.

Mr. FRICKE: (1) Karyokinesis in Cancer Cells; and (2) Secondary Cancer in the Skull.

Dr. HARRIS: (1) Lardaceous Organs; and (2) Aortic Aneurysm.

Dr. LEA: Uterine Specimens.

Mr. MONTGOMERY: Intussusception.

Mr. SOUTHAM: Double Encysted Hydrocele of the Epididymis.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Strangulated Femoral Hernia.—Intestinal Anastomosis.

A MEETING of this section was held on April 2nd, Mr. WILLIAM THOMSON, the President, being in the chair.

Mr. HEUSTON brought forward two cases of Strangulated Femoral Hernia in women over sixty years of age, where, owing to the gangrenous condition of the intestine, it was necessary to excise the intestine and corresponding mesentery. In the first case the symptoms of strangulation had lasted for four days before the operation and the patient was in an extremely collapsed condition; eleven inches of the intestine were removed and the intestine was united by suture. The patient died three days after the operation from collapse, when the intestine was found united, but gangrene had supervened in it for about an inch above the line of suture. The second patient was seen two days after the symptoms of strangulation had come on; eight inches of the intestine were removed and the intestine united by suture; the patient recovered perfectly without complication, the method of radical cure employed in both cases being that advocated some years since by Mr. Heuston and described in Treves's Operative Surgery. In both cases no fluid was contained in the sac, which was intimately attached to the gangrenous contents. Mr. Heuston recommended primary resection whenever possible, instead of the older method of artificial anus, statistics showing that the mortality after artificial anus was about 90 per cent., while that after resection was 47 per cent. He objected to the use of any of the foreign bodies which had been introduced within the past few years, and claimed that the union could be completed by suture in as short a time as by any of these appliances.

Professor BALL brought forward a new pattern of Decalcified Bone Ring for End-to-end Intestinal Anastomosis. It resembled in shape a Murphy's button, but was made in one piece with a deep groove round the circumference of sufficient width to allow the edges of the divided intestine to be involuted, while keeping the peritoneal surfaces in contact, the groove being under-cut to accommodate any surplus intestine. Its essential feature is a lacing suture loosely connecting both ends of bowel round their entire circumference; the ring is subsequently introduced by pulling apart two of the loops, and as the suture is tightened it falls into the groove in the ring, drawing in, and firmly uniting, both edges of divided intestine, while the lips of the groove support the peritoneal surfaces of the intestine in apposition. An additional continuous suture passed round the entire circumference through the outer coats of the bowel only, where the peritoneal surfaces are in contact, completes the union. The decalcified bone was absorbed without difficulty. Four cases were described of the use of this ring, one being a resection of the small intestine for a large gangrenous hernia, one a resection of the upper portion of the rectum, and two being colectomies for malignant disease; one of the latter, a case of very extensive cancer of the transverse colon, died suddenly seven days after operation; the other three made perfect recoveries.—Mr. LENTAIGNE believed Professor Ball's button to be one of the most rapid means obtainable of procuring safe anastomosis, but would not say it was better than Mr. Hayes' method. He could not agree with Mr. Heuston's recommendation that the suture should be used in all cases.—Mr. MCARDLE made some observations in favour of Murphy's button.

CARDIFF PROVIDENT DISPENSARY.—The twelfth annual meeting of the governors of this institution was recently held. The honorary secretary presented the report, which showed that the number of new families admitted as benefit members during the year was 246 and the number of prescriptions dispensed was 20,084. The former showed a decrease and the latter an increase on the numbers for 1895. The number of families now on the books was 1501.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held at Lavender-hill, S.W., on April 14th, Dr. Benjamin Duke being in the chair.—Dr. Caldwell Smith read a paper on the Etiology of Diphtheria, with special reference to two localised outbreaks in Wandsworth, in which he drew attention to the influence of school attendance in causing the spread of the disease.—Dr. Sims Woodhead then gave a limelight demonstration of the Bacillus Diphtheriæ and of the effects of the disease on the nerves, muscles, and other tissues of the body. He emphasised the fact that these injurious effects may occur as early as the third day, and that they cannot be repaired by any amount of antitoxin. He asserted, however, that this, if injected before the third day, will cure 95 per cent. of the cases.—A discussion followed, in which Mr. T. A. I. Howell, Mr. John Gay, Dr. W. Y. Orr, Mr. R. F. Frazer, Mr. A. E. Dodson, and others took part.

Reviews and Notices of Books.

The Practice of Medicine: a Text-book for Practitioners and Students, with Special Reference to Diagnosis and Treatment. By JAMES TYSON, M.D. Manchester: John H. King and Son. 1896.

The Practice of Medicine. By HORATIO C. WOOD, A.M., M.D., LL.D., and REGINALD H. FITZ, A.M., M.D. London and Philadelphia: J. B. Lippincott Company. 1897.

THE publication within a few weeks of one another of two entirely new works on systematic medicine excites both surprise and admiration—surprise that it should be deemed necessary to add to the already teeming list of works of this class, and admiration at the skill and labour expended on such formidable tasks. For the production of a text-book on medicine in the present day must involve a bestowal of time and labour that can hardly be realised by the reader, who expects to find within the pages of the work the very latest information upon the subjects of which it treats, and the author must, if he be desirous of justifying the claims of his book to consideration, have been most diligent in supplementing his individual experiences with the results of recent investigation. We do not wonder, therefore, that Dr. Tyson in his prefatory remarks should say that the preparation of his book has been the product of years of labour, and we trust that he will find his efforts rewarded by the appreciation which his book will doubtless receive. Of the two works before us, undoubtedly Dr. Tyson's is the more exhaustive and the more ambitious, and it is evident that he has endeavoured to maintain a true proportion between the separate departments of the subject. An interesting feature is the introduction of a concise historical account of the diseases which are dealt with. The infectious diseases are first considered, the subject of typhoid fever opening the volume. We note the approval given to the bath treatment of typhoid patients, and the author's deprecation of the prescription of antipyretic drugs, whilst some excellent practical instructions are appended for the guidance of nurses in preventing contagion. As an instance of the "up-to-date" character of the book it may be noted that there are some paragraphs upon the serum treatment as introduced in 1896 by R. Pfeiffer and W. Kolbe. The final passage of the article is significant: "The *antiseptic treatment* has not a truly rational basis, while the extravagant claims of its advocates discredit their results." The malarial fevers receive adequate notice, including a full description of the "malarial parasite." In respect to cholera the importance of bacteriological examination in diagnosis is insisted on, and directions are given for carrying this out. Under the section on "Treatment" mention is made of M. Haffkine's results of protective inoculation, which is considered to be very promising, and detailed instructions are given as to prophylaxis in dealing with the sick. As is to be expected, the serum treatment of diphtheria receives attention, and it is justifiably held that its introduction has considerably modified opinion on the prognosis of this disease.

Passing over many pages, we come to the sections devoted to Diseases of the Digestive System, where we find under the head of "Diagnostic Technique" a full description of the methods for the chemical examination of the gastric contents that have been mainly familiarised by the writings of Ewald. It is owing to the introduction of these methods that amongst the varieties of gastric dyspepsia it is now legitimate to deal separately with "hyperchlorhydria," to which the author devotes some pages, although he is careful to point out that the same condition may also be met with in organic disease. The "diarrhœas of children" are, we are glad to see, discussed apart, and they are distinguished as depending on at least three different conditions—namely, acute dyspeptic diarrhœa, cholera infantum, and acute entero-colitis. Appendicitis receives ample notice, being introduced by a very interesting historical survey of the evolution of knowledge concerning typhlitis and perityphlitis, and full justice is done to the acumen of the present esteemed President of the Royal College of Physicians of London in early recognising that the appendix was a constant starting point of cæcal inflammation. Three "degrees or stages" of appendicitis are discriminated by the author—(*a*) catarrhal, (*b*) ulcerative, and (*c*) interstitial or parietal. Dr. Tyson speaks very judiciously about the period and indications for surgical intervention, and we commend the following dictum to the consideration of surgeons as well as of physicians. He says (p. 307): "It must be admitted that it is not always easy to lay down a rule by which operation shall be determined, for it is not only that we must know when to operate to save life, but also that we must know when not to operate in cases so severe that operation will be futile, and it is due to the operation that it should be saved the opprobrium of such futility. Certain it is, too, that in cases where operation is of no avail death will be hastened by it, the depressing effect of etherisation co-operating to hasten the fatal end." The various forms of intestinal obstruction are succinctly described and their differential diagnosis discussed. The subjects of gall-stones and affections of the bile-ducts precede that of diseases of the liver, where, it may be remarked, the two forms of cirrhosis are treated together, although the author does admit that the "hypertrophic" variety is in the main etiologically, as well as clinically, distinct from the "atrophic" form. The sections devoted to diseases of the respiratory organs and to diseases of the heart and bloodvessels call for no comment, save that they appear to be exact and well planned, especially as regards the articles on croupous pneumonia, pulmonary tuberculosis, malignant endocarditis, and aneurysm. Diseases of the blood follow, wherein we find separate mention made of splenic anæmia or pseudo-leukæmia, a condition well worthy of extended study, especially in relation to its radical treatment by splenectomy. Noting that "exophthalmic goitre" here finds a place amongst diseases of the thyroid gland, and that myxœdema and cretinism are thoroughly dealt with according to the most recent knowledge, we may direct attention to the succeeding section upon Diseases of the Urinary Organs as affording an excellent study of Bright's disease—a subject to which Dr. Tyson has himself been no mean contributor. The "constitutional" diseases, comprising rheumatism, gout, diabetes, rickets, scurvy, and many other conditions, follow. Diseases of the nervous system are next treated without prolixity and with considerable lucidity, a valuable summary of facts in connexion with the relation of infectious processes to such diseases being appended. Perhaps more space might have been devoted to the myopathies, which are described in the next section. The "Intoxications" and "Parasites" form the closing chapters of a work which represents the outcome of much well-directed labour and constitutes a reliable and useful text-book.

We learn from the preface of the joint work of Dr. H. C. Wood and Dr. R. H. Fitz that the former has contributed the section on Nervous Diseases, the articles on Diseases of the Muscles and on the various infectious diseases except diphtheria, dysentery, tuberculosis, leprosy and syphilis, the chapter on Acute and Chronic Poisoning, and all the therapeutics of the book, the remainder of the volume being from the pen of Dr. Fitz. The scope of the work is practically identical with that of Dr. Tyson, for in neither is there any section devoted to diseases of the skin; but the arrangement is different, and so also is the mode of treating the various subjects. There are no bibliographical

Hosted by Google

references in this, the smaller work, and there are very few illustrations. Tuberculosis in all its local manifestations, including pulmonary phthisis, finds a place amongst infectious diseases, whilst considerable space is devoted to functional nervous diseases, including insanity. The sections devoted to thoracic and abdominal affections are such as may be expected from writers who may well claim to rank among recognised authorities in these departments, and although, from the point of view of symmetry, exception might be taken to a disproportionate treatment of some of the subjects, it is always of advantage to receive at first hand the personal experiences of an author. We have no doubt that this text-book will take a worthy place amongst works of its class, for it is comprehensive without being diffuse, and its teaching is rational and accurate. Whilst, then, welcoming these two most recent additions to the literature of general medicine, it is difficult to avoid the thought that the multiplication of text-books must tend greatly to embarrass the student in his choice—a reflection tempered by the knowledge that as between two such works as these he will not suffer by the selection of either.

System of Diseases of the Eye. By American, British, Dutch, French, German, and Spanish Authors. Edited by WILLIAM F. NORRIS, A.M., M.D., and CHARLES A. OLIVER, A.M., M D, of Philadelphia, Pa., U.S.A. Vol. I.: Embryology, Anatomy, and Physiology of the Eye. With Twenty-three Plates and 362 Illustrations. London and Philadelphia: J. B. Lippincott Company. 1897. Pp. 670. Price £1 1*s*.

IT is quite time that an English Encyclopædia of Ophthalmology should be undertaken. The French have in De Wecker and Landolt's "Traité Complet d'Ophtalmologie," of which the fourth and concluding volume was published in 1889, a splendid work of reference brought up with great care and research to that date, and the Germans have the invaluable "Handbuch der Gesammten Augenheilkunde" in seven volumes of Professor von Graefe and Professor Saemisch, which was completed in 1877. But the English student unable to read French or German has been compelled to content himself with the text-books of Berry, Juler, Swanzy, Noyes, Roosa, or the smaller vade-mecums of Lawson and Macnamara. Excellently written as these are, they all attack the subject from the purely practical side. Not one of them contains an exhaustive account of even such large subjects as the anatomy and physiology of the eye, the development of the eye, congenital malformations and abnormalities of it, or describes the relation of ophthalmic disease to the general affections of the system, whilst many important subjects are only glanced at and indicated rather than discussed. The present System of Ophthalmology appears under very favourable auspices. The firm by whom it is published is a liberal one and has spared no expense in illustrations, in type, or in the general get-up of the volume. The editors are gentlemen of high position and large knowledge, and the list of contributors is in itself a promise that the several articles will be well and conscientiously written. With the best men of six nations this System should surpass all its predecessors in fulness and in accuracy. During the last ten years great advances have been made in almost every branch of ophthalmic work, and we sincerely wish success to Dr. Norris and Dr. Oliver in their great undertaking.

The present volume contains eleven articles, the enumeration of which, with the names of the writers, will give some idea of the plan and scope of the work. 1. The first article is by Dr. John Ryder of Philadelphia (to whose premature death the editors refer), who contributed the section on the Development of the Eye. 2. Dr. Thomas Dwight of Boston gives the Anatomy of the Orbit and the Appendages of the Eye. 3. Dr. Frank Baker of Washington, the Anatomy of the Eyeball and of the Intra-orbital Portion of the Optic Nerve. 4. Dr. George Piersol of Philadelphia, the Microscopical Anatomy of the Eyeball. 5. Dr. Alexander Hill, of Cambridge, England, the Anatomy of the Intracranial Portion of the Visual Apparatus. 6. Mr. William Lang and Mr. E. Treacher Collins of London supply the article on Congenital Malformations and Abnormalities of the Human Eye. 7. Dr. E. Jackson, of Philadelphia, writes that on the Dioptrics of the Eye. 8. Dr. J. McKeen Cattell, of New York, that on the Perception of Light. 9. Dr. Eugen Brodhun, of Berlin, discusses Binocular Vision, Conflict of the Fields of Vision, and Natural Size of Objects, &c. 10. Dr. W. Thomson, of Philadelphia, assisted by Dr. Carl Weiland, of Philadelphia, describes Normal Colour Perception; and lastly (11), Dr. Carl Mays, of Heidelberg, gives the Photo-chemistry of the Retina. It would, we fancy, have astonished Mackenzie, Tyrrell, or Lawrence to find that the united labours of three men were required to give a satisfactory account of the second pair of cerebral nerves, and to describe them within the eye, in the orbit, and in the cranium; whilst of the subjects taken up in the two last-named articles one would have been dismissed by the older systematists in a couple of lines, and the other would have been unintelligible to them.

The several articles seem to us to have had full justice done to them by their respective writers. It is difficult to criticise them, because, as each author has only a limited subject to discuss and a free hand given to him in regard to space, he has had an opportunity of introducing all recent and reliable knowledge and at the same time to interweave with the facts discovered or opinions expressed by others the results of his own investigations, which cannot easily be dissociated from them. The chief objection, which, however, is not a serious one, is that the articles of different authors are apt to overlap, as in the case of the cornea, which is treated fully by Dr. Frank Baker in his description of the Anatomy of the Eyeball, and not less fully by Dr. George Piersol in the account he gives of the Microscopical Anatomy of the Eyeball. Both accounts are good, but they might have been combined and condensed. We are struck with the pains the authors, not of these papers only, but of several of the other articles, have taken to collect statistics and the statements of many observers where there are differences in the observations that have been made. Thus in Dr. Baker's article it is given in the text that according to Krause the index of refraction of the cornea is 1·3523, that of distilled water being 1·3358; but in a note it is added that other authorities have given somewhat different figures—Charles Chossat, for example, giving it at 1·33, Aubert at 1·377, L. Matthiessen, 1·3754, and A. Macalister at 1·3825, with in each instance the correct reference, all of which means careful literary work. Yet we observe that Dr. Jackson, in his article on the Dioptrics of the Eye, gives a number which coincides with none of them—viz., 1·3365. There is a similar comparison of the data given by different observers in regard to the thickness of the cornea at the periphery and at the centre, and in regard to the relative length of the several axes of the eye. Both Dr. Baker and Dr. Piersol admit a dilator as well as a sphincter pupillæ muscle, resting their opinion partly on microscopical and partly on physiological grounds. The article on the Dioptrics of the Eye, written by Dr. Jackson, who is known to have devoted great attention to them, is, of course, excellent, but it is short and keeps very strictly to the subject, probably because such subjects as astigmia and other defects of vision will be considered in separate articles. He originally recommended, and still advises, that in adding to the metric series the preservation of the simplicity of the system should be maintained by making the interval one-eighth dioptre, which gives an

Hosted by Google

exact division of the interval previously adopted. The lenses between 1 and 2 dioptres would therefore be 1·12, 1·25, 1·37, 1·50, and 1·75. The article on Normal Colour Perception, by Dr. Thomson and Dr. Weiland, will be read with interest. It contains an account of the most recent views of Helmholtz, with a running commentary upon them. Of the remaining articles, as those of Mr. Collins and of Mr. Lang, of Dr. Mays, Dr. Brodhun, Dr. Dwight, and Dr. Cattell, it is sufficient to say that they contain a vast amount of information not easily accessible elsewhere, and invaluable to those who are engaged in the study of ophthalmic disease.

Sanitation and Health. By Brigadier-General R. C. HART, V.C., C.B., R.E., commanding a district in India. Revised by Brigade-Surgeon-Lieutenant-Colonel T. H. HENDLEY, C.I.E., M.R.C.S. Eng., L.R.C.P. Lond., &c., Administrative Medical Officer, Rajputana, and Residency Surgeon, Jeypore, &c. Third Edition. London: Wm. Clowes and Sons, Limited. 1897. Price 1*s.* 6*d.*

THIS small volume is authorised by the War Office for use in all army schools, which is in itself a sufficient indication of the estimate which the military authorities have formed of its merits. We have read it with much gratification: it affords a large amount of information in a condensed and simple form on subjects which it concerns all ranks in the army to know something about. It makes no claim to originality, but it is carefully and correctly compiled. The pamphlet owes its origin to the fact that (as he then was) Colonel Hart, who was in command of the Rohilkund district in 1888, when there was much sickness during the rainy season among the troops stationed at Ranikhet, delivered a lecture to the soldiers in the station; and this lecture has since been revised by Brigade-Surgeon Lieutenant-Colonel Hendley at the lecturer's request. The volume treats of a number of evils which are always present in India, and points out in intelligible terms how much it lies in the power of every individual to safeguard himself and others against them by the exercise of proper care and a little thoughtfulness. Its merits in these respects, which are undoubted, must have been generally recognised, or it would not have reached a third edition.

There is still room, however, in our opinion, for the production of a work for the general use of soldiers which should deal in their own language with personal hygiene in army life in India; that is to say, in a style so familiar, simple, clear, and practical as to be popular among them. A man like William Cobbett, who had himself served as a soldier in the ranks of the British Army, could, for example, have written a work such as everybody would read; and that it would be eminently useful there can be no doubt. A treatise of this sort need not be a big work, for that in itself would destroy its value; it should not be scientific in tone, but free from moralising and technicalities, long words, and attempts at fine writing; moreover, it should be familiar and simple in style, with pertinent anecdotes, crisp illustrations, and humorous references interspersed here and there—appealing to the common sense and moral qualities that are common to all except the basest and most degraded. There is no reason why one great class of disease, omitted from the work under notice, should not be introduced. Rudyard Kipling has given us a true insight into the nature and character of Tommy Atkins as he actually is and has indicated the way in which he can best be approached. In spite of all his faults Tommy is a strong man and a true man and really a grand fellow. Why should we not tell him the truth about things and prove to him that he need not be a fool, and that if, like the rest of us, he is an animal, he need not be a brute? We have an idea of how such a book as we are contemplating could, and should, be written, and we put forward our suggestion in the hope and belief that some medical officer with knowledge of the soldier and some experience of the tropical service will act upon it. The kernel of the work must consist of facts and figures stated in their shortest and most graphic form and in large type as headings to chapters. This might be followed by a statement to the effect that, "Nor did this state of things end here. It is bad enough that out of an army of such a strength so many men should be deprived of their liberty, should be sick and in pain, and passing weary nights in hospital, instead of amusing themselves outside; but this is succeeded by ....." Then should follow an anecdote or story drawn from real life, and this again by an answer to the soldier's inquiry, "Well, what do you want me to do?" in which the necessary advice is given in terse, plain terms. At soldiers' ages men are restrained by thoughts of home, their mothers and their sweethearts, when they are not by religion; and if reference be made to such subjects in judicious touches here and there, and maudlin sentimentality be avoided, the influence and effect might be salutary and good.

The Law of, and Practice in, Lunacy. By A. WOOD RENTON, M.A., LL.B. Edinburgh: Wm. Green and Sons. London: Stevens and Haynes. 1896.

THIS is a very voluminous book and contains what appears to be a very full collection of statutes, which have been carefully and we should think skilfully annotated. It is timely, having regard to the period which has elapsed since the publication of the last edition of Mr. Pope's book upon lunacy—for Mr. Pitt Lewis's work of 1895 comprised but a meagre collection of statutes, and thus left a gap which Mr. Wood Renton has now filled. His work is probably more interesting and useful from the point of view of the practising lawyer than from that of the medical jurist for the dissertation and systematic statement of the law are by no means in proportion, in respect either of bulk or comprehensiveness, to the volume of the book, which is made up mainly of the statutes and annotations thereupon. Thus we look in vain for any systematic treatment of the topic—all important from our particular point of view—of the care and custody of the insane; nor have we succeeded, even with the help of the index, in discovering the latest utterances upon the theme, painfully interesting to practising medical men, of actions for false imprisonment. These references are sufficient to show that this big book is not free from big lacunæ. Even in the matters that are treated systematically we find ourselves tempted to complain that greater thoroughness was to be desired. Thus Mr. Renton arrives as the result of a very brief review of the legal test of lunacy at the conclusion from which as medical jurists, we should strongly dissent, that "there is a steady approximation towards the only uniform test of lunacy which is desirable or possible—viz., was the person whose act is in question able to understand its nature, and to pass a fairly rational judgment on its consequences to himself and others, and was he a free agent so far as that act was concerned?" Now, this strikes us as being very inadequate. In the first place the question of lunacy is in many cases not a question of an act and its consequences at all, but a question of the individual's condition and the duties which that condition imposes upon his neighbours. For these cases Mr. Renton's only possible test affords no criterion whatever. In the next place, in order to answer the question which he propounds as the test, it is necessary first to ascertain whether the person in question was sound in mind or no. If sound he must be presumed able to understand the nature of his act, &c., but not

Hosted by Google

otherwise, so that the criterion of soundness must be applied first and from the reaction to that criterion an answer to Mr. Renton's question may be deduced. But it is idle to say that the criterion for testamentary capacity is the same, or tends to become the same, as for criminal responsibility, or this again to be identified with the test of susceptibility for medical treatment or necessity for control. All these things are so radically different *inter se*, that although practical convenience is consulted by treating them all as phases of one condition identified as lunacy, only mistakes and confusion of ideas are fostered by suggesting that they are all so similar in character as to be recognisable by a common test.

We have referred above to the general excellence of Mr. Renton's notes upon the statute law. It is due both to him and to our readers to point out that in the table of statutes prefixed to the book there is on page 63 an unfortunate printer's error, which has resulted in producing some confusion between the references to the Lunacy Act of 1891 and the County Councils Act of that year. The latter is not of great importance from the present point of view; whereas the former is, by reason of its date, one of the topics for which Mr. Renton's book will be most frequently consulted. The slip occasions some perplexity, which cannot well be cleared up by way of explanation, but can easily be set right by any reader of the book whose attention has been drawn to it.

LIBRARY TABLE.

The Drainage of Villages. By WILLIAM SPINKS, Assoc. M. Inst. C. E., &c. Second Edition. London: Sanitary Publishing Co., Limited.—Of a subject which is unquestionably one of the most pressing social problems Mr. Spinks' work forms a useful epitome, presenting in a very small compass a large amount of practical information illustrative of what is considered to be the best practice of to-day. It is throughout well supported by references to the best authorities, whilst the several tables given, together with collated extracts from the numerous by-laws dealing with the question, form by no means the least valuable part of Mr. Spinks' little manual. The ground covered in the four divisions into which the book is separated is considerable and presents a clear, if rapid, sketch to those interested who cannot find opportunity for the study of more voluminous text-books, and will certainly be found convenient for reference by a great number of others engaged in such work. It must, however, be added that, though in towns the disposal of sewage by means of a regular system of water-carriage would seem to be a matter of necessity, it is certainly open to serious question whether its universal application to rural districts might not prove anything but an unmixed blessing.

The Idiot: his Place in Creation and his Claims on Society. By Sir FREDERIC BATEMAN, M.D. Aberd., LL.D. Second Edition. London: Jarrold and Sons. Pp. 120.—Sir Frederic Bateman explains in his preface that the arguments contained in this essay formed the nucleus of an address advocating the claims of the idiot upon the philanthropists of East Anglia at a public meeting held in Norwich in support of the Eastern Counties Asylum for Idiots. In addition to much technical matter in reference to consanguinous marriages, parental intemperance, overpressure in education, and other factors having a causal relationship to idiocy, the author shows how the study of the idiot is calculated to throw light upon the abstruse question of the connexion between matter and mind, and that the whole subject is fraught with interest not only to the philanthropist but to the theologian and to the political economist. Sir Frederic Bateman's definition of idiocy is in our opinion an excellent one both pathologically and psychically. It runs as follows: "An idiot is a human being who possesses the tripartite nature of man, body, soul, and spirit, σῶμα, ψυχὴ, πνεῦμα, but who is the subject of an infirmity consisting, anatomically, of a defective organisation and want of development of the brain, resulting in an inability, more or less complete, for the exercise of the intellectual, moral, and sensitive faculties." A strong distinction is also drawn between idiocy and insanity; this point is especially recommended to the careful consideration of the legislators of the country. The whole book is most charmingly written. The arguments are sound and expressed in phraseology which can be understood by the laity, whilst at the same time losing none of their force for presentation to the professional mind. We sincerely wish that the work may carry out the intention of the original address—namely, to claim sympathy for the institution in support of which it was written — and at the same time draw attention to the true state of the sufferers in the institution, who, like all those similarly affected, "have the germ of intellectual activity and of moral responsibility, and this germ, cherished and nourished by the genial warmth of human kindness, fenced round and protected from the blasts and buffetings of the world by the cords of true philanthropy, and watered by the dew of human sympathy, although possibly only permitted to bud here, is destined hereafter to expand into a perfect flower and flourish perennially in another and a better state of being."

Who's Who, 1897. First year of new issue. Edited by DOUGLAS SLADEN. London: A. and C. Black, Soho-square. Price 3*s.* 6*d.*—This is a useful work of reference, containing, in Part 1 at all events, a variety of information which everybody ought to know and very few people do know. The book, however, is not free from inaccuracies. For instance, it states that Mr. Ernest Hart was for "several years co-editor of LANCET." This is quite incorrect. Mr. Hart was at one time a member of the sub-editorial staff of this journal, but he was never co-editor. Dr. James Wakley succeeded his father, the Founder of THE LANCET, as Editor, and on Dr. Wakley's death in 1886 the present Editors, Thomas Wakley and Thomas Wakley, jun., became responsible for the control of the journal, of which there have been no other editors or "co-editors." The preface to the book is amusing. Does anybody really often ask himself, "What paper is it that 'Madge,' or 'Logroller,' or 'Red Spinner' writes for?" Mr. Sladen also tells us that "certain men and women whose untimely death has left a great gap filled in their biographical forms before they went." We should have thought it sufficiently obvious that they could not have done it afterwards, but anyway the editor has not included anyone not living. The most entertaining part of the book is the section called Biographies, as the biographies are for the most part autobiographies, and in many instances the amount of information given is in inverse ratio to the importance of the giver or subject.

The Swedish System of Physical Education. By THEODORA JOHNSON, Principal of the Swedish Institute, Clifton, Bristol. Bristol: John Wright and Co. Pp. 79. Price 3*s.* 6*d.*—This small book gives a good description of the Swedish system of physical education written by one who is well qualified for the work, having had twelve years' experience of it in England and of observations made in Sweden. The objects of the exercises and the methods of performing them are plainly and fully set forth, and the descriptions of the movements are aided by outline drawings. It seems a pity that less cumbrous terms for the exercises could not be adopted; thus, "arch stoop sitting trunk upraising," or "forward arch lying armflinging," are unwieldly. The insertion of verbs would make the title longer but more explicit. Some of the observations made by the author

Hosted by Google

are much to the point, and we cordially endorse them. For instance: "When we find that a doctor gives any man or woman *six lessons* in which to acquire the requisite knowledge of anatomy, physiology, disease, and its treatment by manipulation, and grants, forsooth, a certificate by means of which such person trades upon the ignorance of a gullible public, causing pain and exhaustion, if not serious injury, and so brings 'massage' into sorry disrepute ..... a grave responsibility is incurred." With the condemnation of such a practice we thoroughly agree. It is now too common an occurrence for medical men to teach nurses massage and to take fees from them which they can barely afford, the number of lessons given being absurdly few, and yet their pupils blossom forth as "certificated masseuses" only to live a life of poverty, the market being terribly overstocked. We also agree with the author's remarks in respect to Ling's and Zander's methods, believing that the "delicate manipulations of a highly-developed human hand" are superior to mechanical appliances. With one observation we are not in accord—namely, when the English medical profession is charged with "insular prejudice against anything branded as 'foreign.'" There is probably no country in which the medical profession is so open to receive instruction from, or the results of observations made by, foreign observers as England. The state of our medical libraries is proof of this, where the periodical literature as well as monographs and treatises from all countries are eagerly collected.

Zalma. By T. MULLET ELLIS. London: Ash Partners, Limited.—Mr. Mullet Ellis in this work reminds us by turns of Miss Corelli, Lord Beaconsfield, that immortal work "Codlingsby," Crookshank's Bacteriology, various "penny bloods," "Jack Harkaway," and the earlier effusions of Ouida. But we will credit him with having evolved a simply amazing story, of the *roman à clef* type. Zalma was beautiful and extremely wicked; she also wore the most magnificent clothes, the descriptions of which are enough to make Mrs. Aria or "Virginia" green with envy. The following is her presentation dress, and having read the account of it we can only wonder that she was admitted. "She was in the loveliest pink gown, covered with a mass of old Brussels lace, softened yet more with the softness of fur and feather, and brightened with the damask light of watered silk, revealing, whilst it still concealed, her pulsing busts, which hid behind the down of fur and lace as though they were moons about to appear from masses of feathery clouds." After passing through various vicissitudes, such as a secret marriage, living with the wicked nobleman of the story as his mistress, when she wore a satin dressing-gown with "the allurements of an opening frill," she took to bacteriology, and, having being brought up as an anarchist, bethought herself of working universal destruction by scattering noxious bacilli broadcast, and accordingly cultivated anthrax bacilli in tubs (*sic*), intending to disseminate the cultures over the land by the aid of balloons. However, her scheme was nipped in the bud, and after a Bohemian ball she committed suicide. Mr. Mullet Ellis has taken some trouble to get his bacteriology correct, and for this he deserves praise, but his book is a fine specimen of burlesque.

SUPERSTITION IN THE WEST OF ENGLAND.—The *Western Morning News* reports a remarkable case of superstition. A young woman in Penzance had suffered from "fits," and as a remedy she procured a live toad, placed it in a bag, hung it round her neck, and carried it next to her body. She was also attending a local infirmary and was cured of the attacks, but it is stated that the woman believes that this was only a coincidence and that her strange talisman was the means by which her cure was effected.

THE LANCET LABORATORY.

DIETERICH'S PREPARATIONS.
(AGENCY: M. BUCHNER, 149, HOUNDSDITCH, E.C.)

PREPARATIONS of the following type are interesting as examples of skilful chemical combination. The constituents are so associated as not only to result in a stable mixture, but to yield also a combination in which each is presented in an acceptable and easily appropriated form. Thus in the preparation known as ferro-mangan-iodine-peptonate we obtained conclusive proof of the presence and kind of each of the components indicated. It is a somewhat syrupy, sweet, brown liquid, with aromatic taste, and is offered as a substitute for cod-liver oil, partly on account of the iodine combination and partly on account of its beneficial action upon the processes of nutrition. In another preparation the iodine is omitted, while in a third the metals are combined in the form of saccharate instead of peptonate. From a consideration of their composition there is little doubt that they would serve as powerful tonics in many conditions. Of a like complex composition are the cod-liver oil compounds with iron, manganese, quinine, phosphorus, bromine, sulphur, &c., which again, in spite of this complexity, are clear and stable preparations. Moreover, they are reliably constituted, since we were able to satisfy ourselves as to the presence of each of the medicaments indicated. A preparation of interest on the same list is the extract of malted acorns. It is a light impalpable powder not unlike cocoa, with a pleasant malty and aromatic taste, and turning dark brown on the addition of water. It is practically soluble and contains a large proportion of dextrine, as shown by the iodine reaction. It is said to be indicated in rickets in children and persons suffering from the effects of malnutrition. In the capsules which, when taken together, comprise, it is stated, a remedy for tape-worm, are contained, on the one hand, extract of male fern, and on the other castor-oil. The combination is well known as effective when the extract of male fern is taken at night before rest, followed by the castor-oil in the morning. Lastly, the list of specimens submitted to us concludes with "glue bandages" and "soap glue bandages," which offer certain advantages in the protection as well as treatment of wounds or of abrasions. They may be obtained with or without the antiseptic substances usually employed in such bandages. An improvement in umbilical bandages has been also recently introduced by the same firm.

BLACK'S PATENT FOOD.
(HUGH BLACK, 27, MILL-STREET, ROTHESAY.)

There can be little doubt of the high nutritious value of this food. Apart from the somewhat diverse nature of the ingredients employed, each contributing its own specific food value, the method by which it is prepared is calculated to render it not difficult of digestion. It is first prepared from a mixture of lentils, flour, new milk, and eggs, and made into crisp rusks, which are afterwards ground with maize, oatmeal, and lentil flour, and a little sugar and salt added. The microscope served to confirm this statement in regard to each and all of the ingredients. The food yields a high proportion of essential mineral constituents. The taste is good, and the preparation is evidently a food of high merit.

"EODALB."
(J. W. NICHOLL, 25, HIGH-STREET, BELFAST.—AGENTS: F. NEWBERY AND SONS, 1, KING EDWARD STREET, NEWGATE-STREET, E.C.)

This is a dark, olive-coloured, oily preparation containing iodine in a somewhat modified form to the extent of 10 per cent.

Hosted by Google

and possessing a faint, though distinct, smell of the essential oil of roses. It does not stain, or produce irritation, while it is rapidly absorbed when rubbed on the skin, as is evidenced by the fact that within a few minutes after the application the taste of iodine is experienced in the mouth, and, as we proved, the presence of iodine may be also demonstrated in the urine. The preparation dissolved completely in chloroform without change of colour, but on adding thio-sulphate of soda the iodine was evidently destroyed, the liquid remaining a dark brown. On treating "Eodalb" with alkali a similar discharge of colour took place, and the oil was saponified. The preparation is one of considerable importance in connexion with the external administration of iodine for many obvious purposes. Whilst ensuring the specific action of the drug, it is free from the marked disadvantages of ordinary iodine preparations.

LACTOMALTINE.

Lactomaltine consists, as our experiments have shown, of a powerfully active malt extract combined with milk and cream. It possesses a good, rich, malty flavour, modified favourably by the smooth taste of milk and cream. On dissolving the preparation in water a milky fluid results, in which under the microscope the fatty particles are seen to exist in a finely divided condition. Lactomaltine is also prepared with hypophosphites. The preparation is clearly a reliable one. An introduction of distinct advantage connected with the bottling of this preparation is that a celluloid cap is provided with each bottle, so that the objectionable stickiness met with in constantly extracting and inserting a cork is satisfactorily avoided.

DALU KOLA TEA.

(THE DALU KOLA TEA CO., LIMITED, IMPERIAL WAREHOUSES, LEMAN STREET, E.)

Characteristic of tea that is grown from China seed in Ceylon, the specimen before us yielded a satisfactory infusion of a light character and free from excessive astringent properties. The infusion, though agreeably tea-like to the taste, is not powerful. It yielded on incineration 5·40 per cent. mineral matter, the alkalinity of which was 1·59 per cent. in terms of potash. There was no indication, therefore, of objectionable treatment or sophistication. The caffeine amounted to 2·8 per cent., a figure in accordance with the composition of tea of good quality.

PURE EXTRACT OF MALTED BARLEY.

(THE DISTILLER COMPANY, LTD., 12, TORPHICHEN-STREET, EDINBURGH.)

This extract is characterised by a remarkable degree of concentration and a very agreeable malty flavour, which is quite free from caramel-like taste, in spite of which its digestive activity upon starch is particularly well marked. In short, it possesses all the satisfactory characters of a malt extract that is concentrated with care and with a due regard to the requirements that it is destined to fulfil. This result might be expected of a product made by a firm which, like the above, possesses a large and wide experience of malting processes.

FREEMASONRY: ÆSCULAPIUS LODGE.—A regular meeting was held at the Café Royal, Regent-street, on Wednesday, April 14th, when there was a good attendance of members and visitors. The Master, Thomas Dutton, M.D. Durh., was in the chair. L. Hemmington Pegler, M.D. Edin., H. Simpson Lunn, B.A., M.D. Dub., W. E. Gillson, M.R.C.S. Eng., L.R.C.P. Lond., and G. Newton Pitt, M.A., M.D. Cantab., F.R.C.P. Lond., were admitted to the third degree, and E. Ramsay White, F.R.C.S. Eng., to the second degree. E. H. Ezard, M.D., D.Sc. Edin., was elected Master for the ensuing year, and G. Danford Thomas, M.D. Brux., coroner for Central London, treasurer. A very sociable evening, the pleasure of which was enhanced by the musical members, was afterwards spent.

New Inventions.

A COMBINATION COUCH-CHAIR FOR THE CONSULTING-ROOM.

MANY general practitioners, owing to the limited area of their consulting-rooms, cannot afford space for a couch of convenient size on which minor gynæcological operations might be effectively performed. Medical men in country practice frequently suffer much inconvenience by having to examine patients per vaginam on an ordinary sitting-room sofa. Many combination chair-couches have been invented and patented, but are offered for sale at prices absolutely prohibitive except to the wealthiest members of the profession. The accompanying illustrations depict a chair which combines extreme simplicity of construction with the utmost rigidity and the most absolute comfort. It is an extremely comfortable and ornamental easy-chair which with half a minute's manipulation can be converted into a perfectly rigid couch capable of bearing a dead weight of 350 lb. A practical cabinet-maker tells me that he can make it in excellent materials for £5.

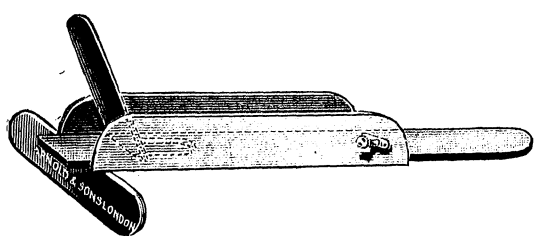
A NEW PATTERN OF SCISSORS FOR PERINEAL REPAIR.

MESSRS. DOWN BROTHERS, of St. Thomas's-street, Borough, have constructed for me a pair of scissors which are much better for flap-splitting operations than anything I have seen before. They are slim but firm in the blades, the points are very carefully made, and the blades slope gradually to the hilt, so that the flaps can be made with one cut each, and therefore will have perfectly true surfaces—a matter of much importance and I fear, not sufficiently attended to. The joint is a beautiful French contrivance which I first saw on a pair of catch-forceps, and have adapted it to scissors, where it has the important advantage of keeping the cutting edges of the two blades in accurate adaptation. It also enables the blades to be unshipped instantly, and is



therefore an advantage for aseptic purposes. From the number of cases coming to me of failure of what is said to have been "Tait's" operation I fear my original instructions are not being carried out, for I have altered the operation in no particular and I have no failures to record. My rules are: cut cleanly and deeply on the white cicatricial lines which indicate the healing of the original tear; insert the stitches deeply *within* the skin margin and miss about half an inch at the bottom of the wound. Use salmon gut sutures and tie tightly. Close the skin wound, if needful, by a few superficial sutures. Keep the vagina clean by washing out with soap and water night and morning, and keep the rectum empty.

Birmingham. LAWSON TAIT, F.R.C.S. Eng. and Edin.

NEW PATELLA SPLINT.

THIS splint I have used with complete success in the treatment of fracture of the patella, and in my opinion it is the best appliance for that injury. It consists of a wooden trough with foot-board, in which I fix the limb. Along the upper border of the patella should be placed a padded cord, with lengths extending down both sides of the leg to a pin or screw fixed in the sides of the troughs at about five or six inches distant from the centre of the fracture. Upon tightening this cord apposition of the upper with the lower

portion of the patella is perfected. No constriction of adjacent tissue occurs to endanger punctual ossification and union. By making the two pins (to which the cord is fastened) as rotating screws tension is easily adjusted for exact apposition of the displaced fragment. The usual V posing of the patient is unnecessary; thus another hindrance to the freedom of circulation is dispensed with—a serious consideration in treating these cases.

FRED. DALTON, L.R.C.P. Lond., M.R.C.S. Eng.

Rottingdean, Brighton.

COMBINED TONGUE DEPRESSOR AND INSUFFLATOR.

A COMBINED tongue depressor and insufflator, invented by Mr. W. Thomas, of Bridgend, Glamorganshire, has been sent to us by Messrs. Woolley, Sons, and Co., Limited, of Manchester. The instrument is in one piece, and therefore easily rendered aseptic by immersion in boiling water, and is provided with a glass screen, which, while allowing a good view of the fauces to be obtained, prevents the operator being infected by the child coughing. The instrument will be chiefly of use for insufflating the throats of children, as, for instance, with sulphur in diphtheria, as inspection and insufflation can be carried out simultaneously. The instrument is strong and well finished, and can be obtained, complete, for 8*s.* 6*d.*

SPUTUM BOX AND STAINS.

MR. FEARNLEY of Harrogate has lately introduced a box containing all the requisites for examining sputum and excreta for the tubercle bacilli. The box contains carbol-fuchsine and acid methylene blue in very convenient drop bottles, slides, cover glasses, cedar oil for mounting, spirit lamp, vessels for water, filter papers, scissors, forceps, &c. The box is accompanied by directions by Mr. Fearnley for the use of the stains which are so admirably clear that anyone without previous training can make reliable preparations if he carries them out carefully, and the whole process need not take more than ten minutes. The stains supplied are of excellent quality. The sputum box will be a great boon to the busy country practitioner, who can easily make reliable preparations for himself at once, and will not have to wait until he has obtained a report from some distant authority. The box can be obtained from Mr. Freshfield Reynolds, pharmaceutical chemist, Harrogate, price 12*s.* 6*d.*

THE PROPOSED CENTRAL HOSPITAL BOARD.

THE following is the text of the petition to be presented to His Royal Highness the Prince of Wales concerning the formation of a Central Hospital Board:—

TO HIS ROYAL HIGHNESS THE PRINCE OF WALES, K.G., &c.

We, the undersigned members of the Medical Profession in London, and others interested in the welfare of Metropolitan medical charities, humbly venture to submit to Your Royal Highness the following short statement, in the hope that Your Royal Highness may be willing to accede to our petition.

In accordance with a communication addressed by Your Royal Highness to the Public, the Prince of Wales's Hospital Fund for London has been established in honour of the Diamond Jubilee of our Most Gracious Majesty the Queen.

To this Fund a very large sum has already been contributed, both in commemoration of Her Majesty's reign, and in the hope that the hospitals of London may be relieved from the heavy financial pressure from which many of them are suffering.

The establishment and maintenance of so large a Fund under Your Royal Highness's auspices will affect the condition of the hospitals of London for many years to come.

For the distribution of so important a public gift, we venture, in the interests of the poor, the Public, and the hospitals themselves, to urge the formation, at an early date, of a Central Hospital Board, including lay and medical representatives of the medical charities of the Metropolis.

This proposal has already received the approval of a large number of the members of medical profession, and of many others interested in the welfare of the poor.

Established with your Royal Highness's sanction, such a Board would do much to promote consultation and coöperation amongst those who are attached to, or engaged in the management of, London hospitals and dispensaries.

Consultation and coöperation thus promoted would enable the hospitals to deal with some of the acknowledged difficulties of their work, as, for instance, the regulation of the out-patient departments.

The Central Board would also be a guarantee to the contributors that the fund would aid the hospitals in the most thorough and satisfactory manner; by furthering the development of medical charity in such a way as to meet the wants of the growing population of the metropolis; and by preventing those evils of pauperism and dependence which medical relief cannot but produce, if it be not administered with care and discretion and in accordance with sound principles of charity.

All this we would submit to Your Royal Highness, and would at the same time beg that, in view of the great importance of the subject, Your Royal Highness will receive a deputation of leading members of the medical profession and others interested in medical charities, in order that they may explain personally their reasons for asking Your Royal Highness to consider the proposal that we have ventured to make.

And your Petitioners will ever pray.

THE LANCET.

LONDON: SATURDAY, MAY 1, 1897.

ABOUT twelve years ago M. GLENARD of Lyons drew attention to the fact that in many cases of neurasthenia, in which gastro-intestinal symptoms predominated, there could be found evidence of downward displacement of the stomach or colon. The condition which he termed gastroptosis or enteroptosis was attributed to an undue relaxation or flaccidity of the abdominal walls, so that the visceral contents of the abdomen lost that countervailing support which normally prevents their tendency to obey the law of gravity in the erect position of the body. A similar explanation was offered of the undue mobility and dislocation of the more solid viscera which occurred with varying frequency in those suffering from enteroptosis, adding perchance to the subjective troubles of this class of patients. Since then the recognition of enteroptosis and its allies has been generally accepted, but it is questionable whether the acceptance of the fact has been put to such practical service as was anticipated by M. GLENARD and those who welcomed his discovery.[1] There has just appeared an essay by Dr. C. SCHWARDT of Gotha bearing on this subject that seems to be worthy of notice, if only to illustrate the far-reaching speculations that it is possible to attach to "GLENARD'S disease," and it may be useful to give some account of this writer's views.[2] These amount to an insistance on the fact that enteroptosis is only one symptom out of many that arise in the course of neurasthenia, whilst in its turn it may lead to other conditions, such as auto-intoxication, that aggravate the primary disorder; the inference being that treatment directed to the relief of enteroptosis or other visceral displacements is of little avail, as the underlying causative element cannot be reached by such measures. For example, the rectification of a mobile kidney, though affording relief to the symptoms directly due to it, may have comparatively little effect in curing the patient of neurasthenia. To emphasise this point he gives the details of a case—one, he says, of some forty examples of enteroptosis that he met with in the first eight months of 1896 (surely a large experience). The patient, a young woman, twenty-five years of age, had suffered from headaches in childhood and adolescence; but an attack of influenza in March, 1895, was followed by dyspeptic troubles, which were further aggravated by a dysenteric attack in the following September. On that occasion the right kidney was found to be displaced and apparently fixed to the abdominal wall to the right of the umbilicus. In October she began to complain of feeling tired and to suffer from pseudo-membranous enteritis (colica mucosa of NOTHNAGEL), eventually taking to her bed on Oct. 27th and remaining continuously under treatment until February, 1896. The symptoms—of a character familiar to most physicians—now became very aggravated. Vomiting was severe and frequent, there were headache, insomnia, abdominal pains, palpitation, pulsating aorta, pain in deglutition, scanty urine, sometimes amounting to anuria, constipation, mental depression, great physical weakness, and emaciation. There was no fever; the pulse varied in rate and regularity as in volume. Examination showed a flaccid abdominal wall, which had become very thin, the stomach descending to the umbilicus, a displaced right kidney (which became mobile again after massage of the colon), and a retroflexed low-lying uterus. Enemata were followed by the discharge of membranous shreds and mucus. For a month treatment was directed to relieve the gastroptosis, and subsequently to keep the viscus quite at rest (by rectal feeding), but the administration of "intestinal antiseptics" to neutralise the auto-intoxication process was of no avail, and narcotics had to be given to produce sleep. The adoption after that time of hydro-therapeutic measures, such as packing, followed by cold sponging, produced a marked change, the vomiting ceasing and sleep soon being naturally procured. The same treatment being continued—with gradual addition of massage, gymnastics, &c.—led to an almost complete removal of subjective symptoms, to disappearance of the enteritis and to a great extent of the enteroptosis, and although the kidney was still mobile the uterus had regained its normal position. In other words, the treatment of the neurasthenia had cured the enteroptosis and the train of disorders attributable to auto-intoxication; and Dr. SCHWARDT urges that it shows that the condition of the skin—which is both an excretory and an important nerve-organ—is of prime importance in the production of many of the symptoms which occur in these neurasthenic states.

Enteroptosis, then, according to this view, is but an incident in the long train of conditions which afford a physical explanation of much of the misery which the neurasthenic, or the hysterical, or the hypochondriac subject experiences. The primary derangement is the "irritable weakness" of the nervous system, when the symptoms seem to be wholly functional—lack of energy, muscular weakness, wasting, and anæmia. Then comes the yielding of the abdominal wall, with diminution of intra-abdominal pressure and resulting tendency to gaseous and fluid accumulation in the stomach and intestines, the walls of which lose their tonicity and dilate, whilst there is also hindrance to circulation of blood and lymph and diminution in urinary and biliary secretions The contents of the intestine delayed in the dilated viscus ferment and produce auto-intoxication, and many of the symptoms are ascribable to retention or absorption into the blood of products that are not properly eliminated. Amongst the symptoms are dyspepsia, vomiting, headache, insomnia, tachycardia, anæmia, and muscular feebleness. Indeed, conditions are set up which increase the primary defect, added to which are the displacements of the solid viscera above referred to and defective action of the skin, which in itself increases the toxic agencies at work. The improvement due to acting on skin and muscles by hydro-therapeutic measures and massage is to be ascribed to the general effect on the

[1] See Revue de Médecine, 1887, p. 75.

[2] Beiträge zur Ætiologie, Symptomatologie, und Therapie der Krankheit Enteroptose - Basedow, Myxœdem - Sclerodermie. Jena: G. Fischer. 1897.

Hosted by Google

nervous system and to the elimination of the toxic materials in the blood as well as the increase of metabolism.

DR. SCHWARDT, however, does not stop here; if he did perhaps there would not be much that is really novel in his thesis, for the efficacy of such measures as those indicated is one of the best accepted facts in therapeutics. He indulges in speculations which certainly have a novel aspect. At first sight it would not seem as if GRAVES'S (BASEDOW'S is the term which he uses) disease and enteroptosis have anything in common. But that is, indeed, his contention. He argues that as the condition of enteroptosis develops there is at first an effort on the part of many organs to compensate for the troubles it occasions, as evidenced by vomiting, diarrhœa, polyuria, intestinal muscular hypertrophy, and increased cutaneous activity. GRAVES'S disease—the heightened activity of the thyroid function—may be regarded as a similar compensating effort, called for to antagonise by the thyroid secretion the poisons which accumulate in the blood from the intestinal disturbance and renal inadequacy. He contrasts the conditions which prevail amongst the subjects of GRAVES'S disease with those present in the neurasthenic sufferers from enteroptosis, and thinks that they are wonderfully similar, whilst he goes further still and draws into the nexus of conditions assignable to like toxic agencies, scleroderma and myxœdema. It is difficult to follow his argument here—we may, perhaps, be pardoned for failing to comprehend it; for although myxœdema may colourably be supposed to be connected with states in which GRAVES'S disease plays a part, it is hard to see how scleroderma comes in unless it be regarded as a result of the cutaneous atony which, in his view, has much to do with neurasthenic symptoms. Yet he has at any rate given an opportunity for the discussion of some of the deeper problems of pathology in which the blood and nervous system take so large a share, and it may be that through some general conceptions of this kind clearer notions will be gained of the essential causes of derangements which are comprised under the term "functional."

IT is only natural that an individual should resent being told he is not performing his duties well. Very few persons are able to kiss the rod and to rise superior to adverse criticism of this sort, and public bodies do but resemble individuals in this respect when they resent the chastening hand of a departmental inquiry. The President of the Local Government Board would, perhaps, have been wiser to have remembered this platitude when he nominated only seven persons, albeit of great ability, to inquire into the existing systems for the maintenance and education of the 12,000 pauper children in the metropolitan area, in response to an agitation which has been going on for some years. He would, we think, have been well advised to have made this committee larger and less open to the criticism that it was not sufficiently representative. The criticisms on the constitution of the committee, published in a pamphlet before us by the guardians of the metropolis, who are, without doubt, the persons chiefly to blame if the education of pauper children be faulty, appear to us to be extremely feeble. The guardians object to two members of the committee because they have had no special experience of pauper schools, and to two others because they have had such experience. They object to Sir JOSHUA FITCH because he is an "educational expert (*sic*) with no special knowledge of Poor-law schools." Nevertheless, he apparently knew sufficient to point out to some of the witnesses that there had been no material addition to the Poor-law curriculum of instruction beyond reading, writing, and arithmetic since 1847. They object to Mr. EDWARD NETTLESHIP because he has only been connected with the schools on ophthalmic questions, which, by the way, is the point with regard to which of all others the guardians' management of these children appears to have most signally failed. Turning to their criticisms of the seventy-five witnesses, who, the guardians say, were "selected without reference to the boards of guardians," twelve were officials connected with schools and twenty-seven were guardians—that is to say, thirty-nine, or more than half, were representatives of the existing system, which stood, as it were upon its trial. The remaining thirty-six consisted of seven inspectors of the Local Government Board, twelve representatives from other educational establishments, eight from the outside public, five from the various boarding-out committees, and four from different emigration societies. The evidence collected, therefore, was of a very representative kind, and we will first inquire what evils this evidence reveals, and, secondly, what would seem to be the best remedies for them.

The evils existing in the present district schools, with which the evidence teems, come under two headings, medical and educational, with both of which, as a journal interested in the health, both of mind and body, of the future men and women of the nation, we are essentially concerned. It has long been known among ophthalmic surgeons, as pointed out by Dr. STEPHENSON, that the majority of young adults "coming for treatment for chronic ophthalmia at the London hospitals have formerly been inmates of the pauper schools"; and Mr. CHAPLIN stated in Parliament only last session, in reply to Dr. FARQUHARSON, that there were even at that time 6 per cent. of the children in the Poor-law schools suffering from ophthalmia, as compared with ½ per cent. under ordinary circumstances. To properly appreciate the causes of the prevalence of ophthalmia in pauper schools the blue-books of the Departmental Committee should be studied, but that it is due to the unhygienic condition of the schools is shown, among other important data, by the fact that a very much higher percentage of children were affected with granular lids amongst those who had resided in the schools for one year or longer than amongst those who had been in the schools for less than one year. Again, the mere fact that between 6 and 8 per cent. of pauper school children are prevented from going up for examination by reason of sickness is sufficient in itself to show that something is wrong in the administration of the schools. That overcrowding, general want of hygienic management and classification of children suffering from sore eyes, sore heads, and other contagious maladies constitute the causal factors in operation is abundantly evident from the various facts mentioned by the different witnesses. Not only does such overcrowding impair the health and eyesight of the children, but it also endangers their lives, as may be seen from the reports of both Dr. SYKES and the medical officer

Hosted by Google

of the Leavesden schools, who inquired into an outbreak of infectious sore-throat in those schools so recently as 1894. The evidence of Dr. BRIDGES, based on over twenty years' experience of the Poor-law schools, which is so amply confirmed by the testimony of others, including the somewhat reluctant testimony of some of the guardians themselves, is well worthy of the most careful perusal. The guardians, in their pamphlet of criticism, attempt to show that the evils referred to belong to "ancient history," but there are ample proofs in the report and evidence that the evils referred to still exist unremedied, though in some of the schools praiseworthy efforts at improvement have been made, and the mere appointment of the Departmental Committee has not been without a salutary effect in this direction. As a matter of fact, the most serious part of the indictment against the managers of the existing schools—that is, the guardians of the poor—seems to be that, although outbreaks of ophthalmia, ringworm, and other diseases traceable to unhygienic management have continually occurred, more has not been done during the past ten or fifteen years to place matters on a better footing, both as regards the overcrowding of the schools and the general want of classification and detail management, the establishment of probation or isolation wards to prevent the introduction of disease, and the like. In some of the schools, we repeat, steps of this kind have been taken, but in general there is a sad deficiency according to the evidence before the committee.

As regards the educational defects, with which we have to deal in a minor degree, but which are intimately associated with the medical and hygienic aspects, it was pointed out by many of the witnesses that the five hours' schooling of a child represents but a very small item in the formation of his character, and that sufficient supervision is not exercised over the children during the remaining nineteen hours, owing, in general terms, to a deficiency and inefficiency in the staff. It is also admitted, even by the guardians themselves, that in these great schools, containing sometimes 1700 scholars, a child loses all trace of his individuality; and that the general trend of the educational scheme is lacking in a technical aspect which not only fits a child hereafter to earn his own living but also by interesting a pupil in his work develops the mind far more than mere book-learning can ever do. The limits of space prevent our discussing on the present occasion the various remedies for these defects, but we propose to refer to this aspect of the question in an early issue.

THE Registrar-General's fifty-eighth annual report, which was published on Saturday last, contains, in addition to the ordinary routine concerning births, deaths, and marriages, certain matters of special medical interest which appear worthy of comment in THE LANCET. Year after year the Registrar-General has had to deplore the large number of deaths which are returned in the registers in such fashion as to be worthless for any statistical purpose, whether in relation to practical medicine or to public health. According to a table at page 12 of the present report we note that out of more than half-a-million deaths registered in 1895 nearly 26,000 were so returned that the causes of death could only be classified as unspecified or ill-defined. In another part of the report it is stated that of the half-million deaths recorded in 1895 as many as 92 per cent. were certified by medical men—of course, compulsorily and without fee. But for the registration of every one of these deaths a statutory fee has been paid to the registrars by the local boards of guardians. In no other country but our own, we opine, would 26,000 fees be paid annually out of public funds for information which has repeatedly been declared to be without scientific value.

For some years past the statistical department has been doing its best to remedy this state of things, and has issued annually thousands of inquiries to medical men respecting death certificates in cases where there was room for doubt whether the actual cause of death had been explicitly stated. That the medical profession have responded handsomely to the appeals from the General Register Office may be gathered from the fact that in the year 1895 there were received more than five thousand replies to medical inquiries, the majority of which contained information which has led to improvements in the classification of causes of death. In that year, as a result of their inquiries, 670 deaths were transferred from vague headings, such as tumour or disease of brain, liver, ovaries, uterus, &c., to cancer; 152 deaths which had been returned as due to pyæmia, peritonitis, pelvic cellulitis, &c., were transferred to puerperal fever; and 91 deaths, which had been ascribed in the first instance to tumour of the brain, were after inquiry referred to syphilis. It is believed, and with good reason, that in the course of years this system of inquiry has led to gradual diminution in the use of vague and unscientific terms in medical certificates of cause of death. In the course of the first half of the current decennium nearly 20,000 letters of inquiry were issued from the General Register Office, and in two-thirds of these cases the classification of causes of death has been altered and improved as the result of these inquiries. The following instances, quoted from the reports, are interesting as showing the variety of names under which serious and important diseases are sometimes disguised in the death certificates. "The terms atrophy of thyroid gland, cachexia, congenital disease, skin disease, constitutional disease, septic disease, pustules, sloughing soft palate, roseola, surgical fever, erythema, visceral degeneration and wasting, were found to have been used as euphemisms to denote syphilis. Abdominal disease, bowel disease, cachexia, disease of breast, disease of face, enlarged glands, exhaustion, organic disease, suppurating glands, and throat disease were used as synonyms for cancer; while alcoholism has been variously disguised as delirium, degeneration of organs, diseased viscera, dysphagia, inflammation of mucous membranes, mania, organic pseudo, general paralysis, toxic palsy, and toxic insanity." In a table at page 22 the result of this system of inquiry and subsequent correction is given for the years 1891–95. The figures show an addition of 8 per cent. to the total deaths from puerperal fever, of 5 per cent. to those from venereal diseases, of 3 per cent. to those from cancer, and of 2 per cent. to those caused by intemperance. On the other hand, they show a reduction of 65 per cent. from the deaths indefinitely referred to tumour, of 46 per cent. from those referred to

Hosted by Google

dropsy, of 39 per cent. from those referred to pyæmia, and of 32 per cent. from those referred to hæmorrhage.

Of the half million deaths recorded in England and Wales in 1895, as many as 13,000 or 2·3 per cent., were uncertified. These uncertified deaths include the deaths of infants who had been attended only by midwives, and those who had been attended by unregistered medical practitioners, as well as the deaths of persons who had received no medical attendance whatever. The proportion of uncertified deaths differs widely at the various ages. Thus, in the year 1895, of the total uncertified deaths, 4390, or just one-third, were deaths of infants under three months of age, and these 4390 deaths were 6·27 per cent., or about one in sixteen of all the deaths under three months old. The proportion of uncertified deaths falls abruptly to 2·49 per cent. at three months and under one year of age, and afterwards more steadily to a minimum of less than 1 per cent. at ages from fifteen to thirty-five years, after which the proportion gradually rises as age advances. In the metropolis and in Middlesex less than 2½ per cent. of the deaths of infants under three months old were uncertified, but in eight counties the proportions were over 10 per cent.; whilst in Herefordshire the proportion was 20 per cent. It may be remarked that the proportion of illegitimate to total deaths is high in most of the counties possessing high ratios of uncertified infantile deaths, but in almost every case the mortality of infants under one year of age, compared with the total births, is below that prevailing throughout England and Wales.

WE publish in another column a petition to His Royal Highness the PRINCE OF WALES from members of the profession resident in London and others urging the formation at an early date of a Central Hospital Board, to include both lay and medical representatives of the medical charities of London. The energy of His Royal Highness of late in forwarding the cause of hospitals—as in the case of Guy's Hospital, and still more in the matter of the Fund established to commemorate the Diamond Jubilee of Her Gracious Majesty QUEEN VICTORIA—justifies all true friends of hospitals in believing that he designs, not only their financial relief and prosperity, but emancipation from those faults of administration which impair their efficiency as a refuge for the poor in their distress and which alienate the sympathy of the charitable, by whom they are mainly supported. Indeed, it is not too much to say that if the PRINCE OF WALES can use his great influence to effect a real improvement in this respect he will do more for hospitals indirectly than directly and will secure the lasting gratitude of those who best understand the uses and abuses of the hospital system. Those members of the profession who sign the petition urging the PRINCE to sanction the creation of such a Central Board have much to encourage them to hope for success. Nearly every inquiry into the subject of the administration of London hospitals has resulted in a similar suggestion. The committee of the House of Lords, which went into the subject so minutely, made this a principal proposal for giving system and principle to a set of institutions which for some years have been posing rather as rivals and competitors in the work of charity than as coöperators. But the suggestion chiefly in evidence is that of the PRINCE'S original letter, in which he so ably set forth the cause of hospitals and their claims to a more wide and extensive support than they have ever received. One paragraph of His Royal Highness's letter to the public may well be reproduced.

"I am aware that the task of distributing the funds when collected will not be without its difficulties. It may be desirable in the future to seek the assistance of representatives chosen by the hospitals, but for the first year we shall rely upon the coöperation of the Distribution Committee of the Hospital Sunday Fund."

This paragraph is of the greatest importance. It shows that the PRINCE, with that common sense which is so admirable a feature of his public work, realises that it is not so difficult, after all, to get money as to make a good use of it, and that, indeed, the way to get it in abundance is to use it well—in other words, to distribute it upon principles which commend themselves to those who are able to give. Clearly the hospitals will have to be represented on this Board, and the representation of the hospitals will not be complete without a representation of the medical staffs, by which alone the real ultimate work of the hospitals is done. The medical staffs of the hospitals have hitherto been very modest and taciturn in the discharge of their duties. But it is generally admitted that the time has come when, in their own defence and in that of other members of the profession, as well as in the interest of hospitals themselves, they must assert their claim to be considered and consulted in the burning questions of hospital administration. We may be sure that the PRINC OF WALES will be ready to admit that the enormous and gratuitous services of the medical profession in hospitals entitle them to be included in that representation of hospitals which he foreshadowed in his historical letter. We may hope, too, that His Royal Highness will go still further and admit that the medical profession as such has a claim to be represented among those to whose assistance he looks for dealing with the "difficulties" of distribution in the future. We hear much of the medical charity of hospitals, but we hear little of the medical charity which is administered elsewhere than in hospitals night and day by the rank and file of the medical profession, and which entitles them to be represented on any Central Board meant to regulate the action and the charity of hospitals. We assume, too, that the public, or the charitable section of it, will be in some way called in to the assistance of the PRINCE and his colleagues in this difficult matter of distribution. The petitioners do well to approach His Royal Highness on this branch of the subject. The time is opportune for doing so, and we very cordially endorse their petition. It may be said that the PRINCE might continue to look to the Hospital Sunday Fund, as he proposes to do "for the first year." We are glad that the PRINCE has so far recognised the claims of the Hospital Sunda Fund or of its Distribution Committee to be regarded in this question of distribution of the Commemoration Fund but unless the administrators of the Hospital Sund Fund show some larger sense of responsibility than they have yet displayed, and some keener perception of the dangers of indiscriminate and pauperising charity, w

Hosted by Google

cannot admit their claim to be considered a Central Board in the sense in which the petitioners use the word or the members of the Committee of the House of Lords intended.

It only remains for us to assure His Royal Highness that the members of the medical profession generally, both in London and the provinces, concur in the prayers of the petitioners. None recognise more cheerfully than medical men the enormous benefits conferred by hospitals, and none are more anxious that they should be well distributed and dissociated from all evils of administration, owing to which those needy ones for whom these benefits were originally intended are passed over, and those who neither require nor deserve them are demoralised.

Annotations.

"Ne quid nimis."

THE PROFESSION IN FICTION.

LARGE and unusual as are their opportunities of reading character and witnessing its response to the ordeal of circumstance, medical men have consistently shrunk from giving their experiences to the world. Their interest is primarily their patient's physical and mental well-being; the facts which come before them in diagnosis and treatment—often, indeed, intensely dramatic, always of value to the student of human nature—must remain undisclosed, as sacrosanct as the revelations of the confessional, in compliance with an obligation embodied for all time in the oath of Hippocrates. The literary layman, however, is not so bound; and in the world of fiction may reproduce professional facts and characteristics leading up to dramatic *dénoûment*, with a freedom only restricted by the laws of philanthropy and good taste. In these days, when the novel is largely usurping the place once monopolised by the pulpit, and all but abandoned (in spite of Addison's suggestion) by the stage, the field of medical experience is more and more cultivated by the writer of fiction, with a success, moreover, measured by the degree in which the individual has been at pains to master the human organisation and to watch its behaviour when face to face with the realities of disease and death. We could signalise more than one successful contribution to this form of fictitious art, but will confine ourselves to its most recent as well as (to our thinking) its most powerful example — "The Dowager's Determination," by Mrs. Severne. The story turns on the decay, intellectual and moral, of a patrician house, the later heads of which have, by an ill-assorted inter-marriage, tainted it with mental disease betrayed in the lives, generally short, of its successive heirs. The dowager, a powerfully-drawn character, sets herself to force back this degenerative current, and, with equal skill and cynicism, effects the marriage of her grandson, Lord Raymore, with a typically prepossessing English girl, Lilian Jardine, the local rector's niece, between whom and the young practitioner of the neighbourhood, Stephen Brand, there had for some time been developing relations more than friendly. Lord Raymore has already shown signs of insanity—signs professionally known to Dr. Brand, but not known by the girl and all but ignored by her uncle, the social ambition of both being proof against any misgiving as to the sacrifice they are unwittingly courting by acquiescence in the dowager's "determination." The marriage takes place, and then begins a series of incidents, each more dramatic than the other, as husband and wife, like the hero of the "Iron Shroud," find their doom narrowing daily in upon them with a "necessity" (ἀνάγκη) as inexorable as that of the Æschylean Trilogy. Mrs. Severne has read widely and deeply in the literature of mental disease, and for a lay writer steers commendably clear of the rocks on which so many literary voyagers in professional waters have already made shipwreck. Lord Raymore is the central figure, but the "hero" in every sense is the young medical man, whose conduct from first to last is that of a chivalrous gentleman as well as a master in the healing art. It would be ungracious to anticipate the reader's interest by forestalling the course and culmination of the incidents, but we may note in passing the felicity with which the local colour of the scenes of suffering is given—"the ears strained to catch the closing of a distant door or the muffled sounds which, in some peculiar way, tell of sickness in a house." Over and above its success in portraying the profession in real life the novel has a special value in powerfully exposing the sin, the actual "crime," as John Stuart Mill called it of promoting marriages regardless of all but social or financial considerations. Mrs. Severne drives her moral home with force and effect, and the tale that gives point to it might be varied almost indefinitely by reading for "madness" one or other of the scarcely less sombre maladies which convert marriage from a blessing into a curse.

THE DECLINE OF THE SCOTTISH UNIVERSITIES.

THERE is no doubt that, tested by the numbers of matriculated students, the Scottish universities have in all faculties been of late years registering a steady decline. The fact is sought to be explained in diverse ways. In the arts faculty particularly the standard of proficiency on admission to the curriculum has been too low and the instruction given has savoured more of the upper form in schools than of the university, so that for the higher education the more aspiring youth prefer Oxford and Cambridge to Edinburgh or Aberdeen. Another reason for the diminished numbers in the same faculty is the poverty of the career open to the graduate, the teaching profession being almost the only *métier* (and that an underpaid one) in which his qualifications are marketable. Then, again, the Scottish M.A. has never carried with it the same guarantee of thoroughness and academic status implied by that of Cambridge or Oxford. True, the degree attests an acquaintance—it can hardly be called a familiarity—with a greater variety of subjects, but extent of superficies has been gained at the expense of depth and by ignoring the *prima cura* of all university culture, which, according to Froude, is that of teaching the *alumnus* "to know what knowledge of a subject means." The entrance examinations, moreover, which by their laxity ought apparently to attract the freshman in greater force, really repel the increasing number of those who demand what a university ought to give — association with well-trained students competing in generous rivalry for qualifications and honours worth the contest. Yet another cause of the Scottish decline is the excessive number of "seats of learning" north of the Tweed, two at most being all the North Briton requires if his needs are measured by population and the prizes in life within his reach. Again, the lecture system—so traditional a favourite in Scotland — is an effete survival from the Middle Ages, quite necessary, no doubt, when the art of printing was still young, but preposterously overdone, particularly in medicine, to the weariness of the student and the waste of his precious time. "Eyes first, hands next, ears last," the memorable maxim of that excellent teacher, the late Sir G. M. Humphry of Cambridge, is now becoming the practice in all schools, especially in those where applied science and the qualifications required for the noblest of "work-a-day professions" are demanded and furnished. The severe competition of the provincial universities in England, which are

Hosted by Google

very flourishing, has not received due attention from the authorities of the Scottish Universities. One final reason which, strange to say, has escaped the Scottish mind in accounting for the university decadence is the undoubted fact that for the last fifty years the competition of English and Irish schools has become more successful mainly owing to the reinforcement of their teachers and examiners from their northern sister. The academic Saturn north of the Tweed, like his antique prototype, is being devoured by his own progeny. For this Scotland has her own lack of professional outlets to thank. The best of her sons are precisely those whom she can least powerfully attract to her own service. Her whole academic and professional life is at present being painfully reminded of its defects under latter-day competition and requirements, but we can hardly think her so unequal to her better self as to suppose that having discovered the kind and degree of the bane she will be unable to devise the appropriate antidote.

ALLEGED NEGLECT OF A SICK PAUPER.

THE Woodbridge board of guardians have been discussing a complaint against one of their medical officers, Mr. Edwardes-Ker, for delay in visiting and in sending medicine to David Gardner. A letter alleged to have been sent by the relieving officer does not seem to have reached Mr. Edwardes-Ker. There were, besides, other discrepancies of statement. The guardians very properly appointed a committee to find out the facts of the case. We hope the guardians will make their investigation complete, and consider the means whereby medical officers are or can be informed in proper time of the illness of patients or can send to them medicines with sufficient despatch. Without judging the medical officer or his accusers, it seems to us that after the defects in these means have been considered there will be little blame attaching to Mr. Edwardes-Ker.

"A NOTEWORTHY INQUEST."

OUR attention has been called to a paragraph in the *Watford and West Herts Post* commenting on the inquest, which we reported in our issue of last week, held at Bushey by Dr. Lovell Drage on a patient who died in child-birth while being attended by a midwife, Miss Alice Mary Jennings. Our readers will remember that the case was one of severe accidental hæmorrhage, and that, according to Miss Jennings's own evidence, three or four quarts of blood had been lost before she arrived, though there was not much bleeding going on when she first saw the case, which was at 7·45 A.M. The head was presenting; she plugged the os lightly with a soft silk handkerchief, and in about an hour afterwards, when the os was dilated, she ruptured the membranes, and brought down first one foot and afterwards the other—in other words, performed podalic version. The child was born at 12.30 mid-day. The patient died about 4.30 P.M. the same day. The post-mortem examination showed that the cause of death was pulmonary embolism and that the case had not been one of placenta prævia, as the midwife had supposed, but that the placenta had been normally situated. The jury found that the midwife was to blame, among other things, for not calling in a medical man in the first instance as soon as she saw the serious nature of the case. It appears from the paragraph in our contemporary above referred to that notice has been given that "Miss Jennings is and will be at perfect liberty to fulfil all existing and future engagements, even if the Obstetrical Society should see fit to recall her diploma." Probably so far as the legal aspect of the matter goes this is so. If those who had engaged her previously, being now aware of the case that formed the subject of the inquest, are still willing to be attended by her they are at liberty to be so attended. The comments which our contemporary makes on the matter seem, however, to call for some notice. In the following passage, for instance, our contemporary misses the point altogether: "Nothing has been done or left undone that could have contributed to the death of the deceased, only a rule of a society has been broken because nothing occurred to show that there was any necessity to comply with it. General sympathy will therefore be with Miss Jennings, who can scarcely be blamed when a doctor would be free." It is not the question whether Miss Jennings adopted the best treatment in this particular instance or not. The point is that in all serious cases—and there could hardly be a more serious one than a case where three or four quarts of blood are lost at the onset of labour—it is the midwife's duty to call in a qualified medical practitioner without delay. It is obvious that a properly qualified member of the profession must necessarily, as a general rule, be a better judge of what should be done in a serious case than a woman whose education is only adapted to fit her to attend ordinary straightforward cases efficiently, and to know in what cases to send for skilled assistance. As Miss Jennings admitted, the case in question was one of those in which she was taught to send for a medical man immediately, and it is because she failed to do so that she was censured.

INSANE JOURNALISTS.

"IN several of the English lunatic asylums," says a writer in a French medical periodical, "the management has had the happy and original idea of introducing journalism amongst the inmates as a curative measure, and according to the reports furnished annually the innovation has been attended with the best effects. Some of the physicians even declare that in many instances they have been indebted to the lucubrations of their patients for valuable hints as to the best way of treating them. One demented person, for example, obstinately refused to take any food, and with equally invincible stubbornness declined to furnish any reason for his refusal. There was no difficulty, however, in persuading him to commit his thoughts to paper, for apparently the *cacoëthes scribendi* is quite as powerful amongst people who have lost their wits as it is amongst those who have contrived to preserve them, and at once this individual's peculiar delusion was made manifest. This is what the hitherto intractable monomaniac wrote: 'I desire to be buried as quickly as possible. It is a monstrous scandal that I should be compelled to drag about all over this house a dead and putrefying corpse.' As soon as the bent of the patient's weak-mindedness was thus brought to light he received appropriate treatment, and is said to have eventually recovered." The French commentator selects *The New Moon*, which he justly regards as very appropriately named, for especial commendation, but he omits to say where this journalistic luminary rises. He quotes from it the following passage, which shows, at all events, that a sense of humour is compatible with lunacy; "Wanted for a throne, which it would be indiscreet to specify at present, an Emperor or King who is thoroughly conversant with the business. It is quite useless for the Czar of Russia to reply to this advertisement." We may inform our contemporary that journalism by lunatics for lunatics is by no means a novelty in our establishments for the insane. Writing in 1857 Dr. Andrew Wynter said, with reference to Murray's Royal Asylum at Perth: "Not content with these efforts, they seem to think that they are nothing unless critical, and accordingly they have set up a journal in which they review their own performances. The first number of *Excelsior* is now before us, in which we find poetry, news, and criticisms

Hosted by Google

on music, and contemporary literature; and he who reads with the idea of finding anything odd in this production will most certainly be mistaken, for no one could divine that there was a 'bee in the bonnet' of printer, publisher, and contributor." Anyone interested in the history of lunacy and its treatment in modern times will find much curious information in Dr. Andrew Wynter's article. It was published, together with several other papers by the same author, by Mr. Robert Hardwicke of Piccadilly, in a volume called "Curiosities of Civilisation"—having appeared previously in the *Quarterly Review*.

IDIOPATHIC OSTEOPSATHYROSIS (FRAGILITAS OSSIUM) IN CHILDHOOD.

EXCEPT in old persons fragilitas ossium is a very rare condition. Dr. Griffith relates the following case.[1] A male child was born on June 11th, 1893, after a labour which was neither protracted nor severe. Nothing was noticed until the second day, when it was found that the right femur was fractured. On further examination under an anæsthetic the left was also found fractured at its neck. Both limbs were placed in long splints with silicate of soda bandages. In three weeks union was complete. At the age of three months the right humerus and femur were broken, apparently during a medical examination, which was carried out with due gentleness. Both bones united well. On March 1st, 1894, the child fell forward, but not out of his chair, and sustained fracture of the right femur near the hip. On Sept. 11th, 1894, he broke his left thigh again. Union took place, but two weeks afterwards he broke the bone again. In the spring of 1895 he fell out of his hammock and fractured both femurs. They united well, but three months later the right was again broken. Besides these fractures there were others undiscovered. At times he seemed to have pain in various parts of the body, supposed to be rheumatic; but this was evidently due to fractures, as there were at least one fracture of the left thigh and one of the right forearm found afterwards with angular union. On several occasions he broke his ribs. In all he certainly had twelve fractures, and possibly eighteen. Union was always prompt. No hereditary influence could be traced; both parents and grandparents were unusually healthy. The child was suckled until the age of five months, then fed with cow's milk, and later with food suitable for his age. The general health and nutrition were good. At the age of two and a half years he was a plump, well-developed, healthy-looking boy. He was carried constantly on a stretcher lest sittting him up might produce fracture. The head was decidedly larger than normal. The frontal bones had distinct bosses, suggesting rickets, and the back of the head was flattened, doubtless from the long-continued pressure of an enforced position. There was no beading of ribs, enlargement of epiphyses, on other evidence of rickets. The right arm had a bad angular deformity above the wrist, and the left thigh was similary deformed with eversion of the foot. Curvature of the bones in any part could not be detected. The muscles of the calves were well developed, but the thighs were flabby. The arms were well developed. Advice to the effect that he should be allowed to sit up, to give his muscles the needed exercise, was given. In four months he had greatly improved. He could turn himself over and move his legs freely, and sit upright in the lap. The muscles were evidently gaining strength rapidly. There had been no more fractures. His head, however, seemed even larger, but was not in appearance either hydrocephalic or rickety. After an extensive search through the literature of idiopathic osteopsathyrosis in children, the writer could find but few cases in which the brittleness was greater than, or even equal to, that in this case. He collected fifty-seven cases from which he draws the following conclusions. As to the etiology, inheritance is a marked factor. In eleven it was direct—that is, the disease had appeared in either parents or grand-parents and perhaps in several of the children. In seven others there was a family predisposition without direct inheritance—that is, more than one child were affected, and perhaps some other relatives. There were twenty-four cases in which no family predisposition was recorded. The remaining fifteen are classed as doubtful cases because rickets or other disease was present. Amongst these he places cases resembling the so-called fœtal rickets, and others in which intra-uterine fractures occurred from insufficient ossification. Males were more liable than females in the proportion of forty-seven to nineteen. The disease usually began very early in life, sometimes before birth; in a few as growth advanced. Syphilis and rickets did not appear to have any influence in the production of this strange fragility. Cases in which fracture was secondary to gumma are of course excluded. Where the disease occurs in the subject of rickets the writer considers it to be a case of co-existence and not causation. For in rickets there is a tendency to bend and to the production of green stick fractures; in osteopsathyrosis, on the contrary, the condition is one of extreme brittleness, without any tendency to bend. Osteomalacia shows a similar difference. So-called fœtal rickets is closely allied to osteopsathyrosis, and provisionally placed in this category. Nothing definite can be said of the pathology as the reports of examinations of the bones by different writers are very contradictory. A marked feature of the affection is that union of the fractures is prompt. Pain never precedes fracture as in osteomalacia. The long bones of the extremities, especially the lower, the clavicle, and the ribs, are most frequently broken. In no case was there a fracture of the vertebræ or pelvis. Fractures are entirely independent of the union of diaphysis and epiphysis. In making a diagnosis the presence of any disease primary to the fractures must be excluded—viz., syphilis, nervous disease, osteitis, tumours, &c. Rickets presents many features of its own which enable it to be distinguished. It is questionable if osteomalacia is ever present at a very early age, and it much more resembles rickets than this disease. The prognosis as a rule is unfavourable. The duration of life does not seem to be affected, but the tendency to fracture is apt to continue unabated. In a few, however, it was outgrown. The treatment consists in the administration of alteratives, the maintenance of the general health, and the protection of the limbs. But the muscles must not be allowed to waste for want of use. Union of the fractures should be secured in proper position.

[1] American Journal of the Medical Sciences, April, 1897.

ACCIDENT OR OUTRAGE?

WE fear that the evidence bearing upon the mysterious occurrence of a disastrous explosion in a train at Aldersgate-street Station on Monday night is narrowing down in favour of a dastardly and cowardly miscreant being at large. The theory that the disaster was due to the explosion of the cylinder beneath the carriage containing gas for illuminating purposes cannot be seriously entertained, since on examination the cylinder did not prove to be rent by bursting, but, on the contrary, was indented and intact. If, again, as some have conjectured, it was a portable cylinder of compressed gas in the carriage, where are the remnants? From the accounts of the nature of the explosion given by several witnesses there seems little doubt that the explosive was of the high order and belonged to the "nitro" group. A close examination of the wrecked carriage may perhaps lead to the identification of chemical residues which will enable the experts to say with

Hosted by Google

some degree of certainty what the explosive was. Even, however, assuming that this becomes known, it will still remain a mystery as to whether the explosive was left designedly or accidentally in the carriage. The results were serious enough, and have, unfortunately, led to the death of one of the injured; but worse might have ensued if at that moment trains had been coming and going with the rapidity of a busier time of the day. We sincerely hope that the matter will not prove to be beyond elucidation, and, if the evidence points to outrage, that the scoundrel who perpetrated it may be tracked and dealt with as such a scoundrel deserves.

THE INTERNATIONAL MEDICAL CONGRESS AT MOSCOW.

WE desire to impress upon the attention of our readers the statement made in our columns last week—namely, that the Russian railways have most generously decided to grant free passes on the railways to members of the Congress. This piece of courtesy will greatly reduce the expense of a visit to Moscow, and we hope will induce many members of the profession to attend the Congress who might otherwise have been prevented on the score of expense. It is an opportunity not to be lightly set aside, for, apart from the scientific aspect of the Congress, Moscow is one of the most interesting towns in Europe, and, moreover, unknown to the majority of Englishmen.

THE PLAGUE IN INDIA.

WE are extremely glad to recognise that the latest reports from Bombay on this subject are much more satisfactory. There is a still further decline of the epidemic. The stringent measures for dealing with the disease under the powers of the Epidemic Diseases Act, which have now been enforced for some time, have apparently been justified by their success. We trust, however, that the Indian authorities will not rest satisfied with applying measures for limiting contagion, but that the occurrence of this epidemic will lead them to consider what should be done in the way of sanitary and public health improvements to guard against similar occurrences in the future. These cost money, no doubt, but they do not cost so much as outbreaks of epidemic plague, and they are not only the best safeguards we possess against that disease, but against all other epidemic diseases that may occur.

"PRIMARY CANCER OF THE NASO-PHARYNX CURED BY INJECTIONS OF ALCOHOL."

AN interesting case under the above heading is reported in the *New York Medical Record* of April 17th by Dr. Edwin J. Kuh. The patient was thirty-seven years of age and had suffered from "nose-bleed" and nasal obstruction accompanied by viscid discharges since childhood. The growth was removed by operation, but in less than a month the post-nasal space was again almost completely filled by a soft bleeding mass. Sections of the tumour which had been removed by operation showed the characters of epithelial cancer, the diagnosis being confirmed by Professor Senn. Further surgical interference being considered too hazardous the neoplasm was first injected with unfiltered erysipelas-prodigiosus toxins, from five to twelve minims being employed daily. This treatment proving unsuccessful it was decided to inject alcohol into the growth. At first three minims of absolute alcohol were used, this dose being rapidly increased to thirty minims. "The reduction in size began after the seventh injection, and after the eleventh but few remnants of the growth remained. After a dozen more injections the needle would not penetrate into tissues capable of retaining the alcohol, and after a few additional attempts, at intervals of a week or longer, they were discontinued." Some two ounces of iodide of potassium were given during the later injections, but Dr. Kuh contends that the drug stood in no causal relation to the disappearance of the growth. In February, 1897, four months after the cessation of treatment, the naso-pharynx was found, both by inspection and palpation, to be entirely free from growth.

HOSPITAL REFORM.

WRITING to the *Birmingham Daily Post*, Mr. Lawson Tait says that "we [the profession] are entirely responsible for hospitals, and for all their faults as well as their merits." He maintains that the medical officers of the Birmingham Hospital could make an end of the trouble in a month. As a temporary expedient he suggests that they should assign 30 per cent. of their income accruing from hospital position for the assistance of their "struggling extra-mural brethren." We are sure the "struggling brethren" would decline any such remedy. All they ask from their hospital colleagues is to use their influence to restrict the benefits of hospital treatment to those who need it and cannot afford to pay for it. Neither is it of any use to lay the whole blame on hospital honorary officers. The committees and governors of hospitals are equal or greater culprits. Our contemporary's pages are devoted to a discussion of the whole question of hospital abuse and contain many letters which we have not space to notice at present.

THE ATTEMPT ON KING HUMBERT'S LIFE.

FOR the second time within nineteen years an attempt has been made on the life of the King of Italy. The first—that of Passanante—was political in its motive; the second—that of Acciarito—was prompted by misery. This latter provocative of crime is, unhappily, an increasing one in the Italian kingdom. Hardness of living, with all its attendant evils, becomes year by year a more terrible reality within its borders till it inspires excesses which the law is powerless to prevent. To avoid death by starvation the unemployed artisan will qualify for the prison, where at least he will be fed, with a roof over him and a bed to lie on. "I had nothing to eat and had to do something," was the sullen, cynical answer of Acciarito to his interrogators. Surely there must be "something rotten in the state" where would-be Acciaritos may be counted by thousands. To pose as a great Power, to maintain a colossal standing army and a formidable fleet, to attempt colonial expansion, and to carry its "sphere of influence" to the Antipodes may be justifiable in a nation rich in natural resources and strong in character and tradition; but it is at least premature in one which has barely passed its majority, whose resources, abundant by nature, require all its energies to develop, and to whom self-government, by its very unfamiliarity, is infinitely more expensive than to its maturer and more skilfully regulated neighbours. Italy must alter her tack and trim her sails to other winds if she is to escape shipwreck, aggravated by mutiny on board. The recent general elections have given her rulers a hint in that sense which they cannot ignore. In every constituency—nowhere more than in Turin, the cradle of her monarchy, Milan the centre of her enterprise, and Florence the seat of her culture—the Socialist vote was multiplied beyond all European or Transatlantic precedent. True, that vote was given in favour of candidates exceptionally conspicuous for enlightenment, public spirit, and familiarity with the nation's wants. The majority of those whom it returned were medical men o holders of university chairs, whose one aim in entering Parliament was to ameliorate the masses and reduce that hardness of living which is the fruitful parent of crime. These men are society's best friends, having no

Hosted by Google

sympathy with anarchy or political chaos, but profoundly interested in the conditions that underlie healthy evolution. From them, in the last resort, neither Crown nor Court has anything to fear—the constitutional monarch being, in their eyes, "one who reigns but does not govern," and constitutional monarchy itself a "republic in which the President is hereditary." All they plead for is education on the lines dictated by hygiene; industrial or agricultural employment under the surveillance of sanitary law; the provision of healthy homes and unadulterated food; the reclamation of lands run to waste; the reafforesting of denuded hillsides and the regulation of watercourses running riot in floods shall—among similar reforms—receive the practical attention of the legislature. This is a "crusade," or rather, in the term coined by John Stuart Mill, a "civilisade," in which the paladins are the medical men whose headquarters are the universities, particularly the Subalpine School. Loyal in a sense unknown to the political agitator or place-hunter these men are labouring for reforms which make government of any kind—monarchical or republican—possible; government "broad-based upon the people's will"—a people, moreover, healthy, happy, and contented. Deplorable as was the attempt on King Humbert it will have the effect of driving home the lesson taught by the recent elections—to wit, that there is nothing so fatal to national stability of any kind than a people denaturalised by hardship, insanitation, and the predominance of conditions that make life not worth living. We are glad to see Italy's leading organs commenting in this strain on the recent incident. "L'Italia abbonda di molti miserabili, di molti infelici. È la sua debolezza ed è la forza dei partiti estrèmi" (Italy abounds with many miserable, many unhappy ones. It is her source of weakness, as it is a source of strength for her extreme parties). Let us hope she will take the lesson to heart, not rejecting the warnings of the socialist Sibyl till they are drowned in the crash they had tried vainly to avert.

FOOD-SUPPLY IN PEACE AND WAR.

THERE are peculiar difficulties connected with that section of legislative administration which attempts to insure for the public a pure food-supply. The problem is to be fair to both purchaser and seller. We have always urged that the law should provide that the purchaser be supplied with the exact article he requires. Considerable impetus towards attaining this end would be derived if the suggestions of the Agricultural Guild, of 17, Victoria-street, Westminster, were adopted. This Guild proposes to hold "an important conference" on May 3rd at the Westminster Palace Hotel at 3 P.M. Amongst the subjects to be discussed are the advocation by legal enactment of the sale of (1) English, (2) foreign, and (3) adulterated food products in *separate and distinct shops*. What an admirable idea. The public would then know which shop to go to for an English, foreign, pure, or adulterated article of food. The second subject for discussion is "the serious deterioration in the stamina of English men and women owing to the consumption of non-indigenous and deleterious food." We are not prepared to admit that there is any deterioration worthy of anxious consideration. But the third and last subject for discussion is as admirable in principle as the first. It is "to consider the imperative necessity, on hygienic and economic grounds, for the removal of the milling and baking industries from the slums of London to the open country." The primary aim of the Guild is to realise the admissions of the late Earl of Derby, that the lands of the United Kingdom, which are, on the whole, naturally fertile, were capable of yielding by intelligent tillages sufficient produce to feed our increasing population for hundreds of years to come. Why, then, should we incur the danger, urges the Guild, of depending on foreign countries for our food-supply in times of both peace and war? Happy Guild, with such noble aims and ambitions in view; but have they reckoned with the economics and other equally important aspects of this vast question?

THE SERUM DIAGNOSIS OF TYPHOID FEVER.

THE Corporation of Eccles, in Lancashire, is to be commended for its enlightened policy in providing facilities for the employment of serum diagnosis in suspected cases of typhoid fever occurring in the borough. Work of this kind can only be undertaken by a professed bacteriologist, for fresh cultures of typhoid bacilli must always be at hand for mixing with samples of blood from the patients. It is, therefore, very satisfactory to find that Dr. J. H. Crocker, the medical officer of health, has informed all the practitioners in Eccles that such samples will be examined for them by Professor Delépine of Owens College, Manchester, and that the results will as a rule be made known the day after the receipt of the specimen. The general arrangements will be similar to those which answered so well at Eccles in the case of diphtheria. Pipettes for the transmission of the samples are kept at the town hall, the expense of the bacteriological examination is defrayed by the corporation, and practitioners are recommended to avail themselves of this diagnostic aid at the earliest possible period of the illness. If the case is notified as typhoid fever the fee of 2*s*. 6*d*. will be paid, even if the bacteriological examination gives a negative result. This new development of practical bacteriology promises to be very interesting.

THE ROYAL SURREY COUNTY HOSPITAL AND HOME VISITS.

THE governors of the Royal Surrey County Hospital have, at a special court, adopted the recommendation of the committee to substitute for Rule 90, concerning home visits, the following words: "Out-patients residing within the borough of Guildford and too ill to attend the hospital may be visited at their own homes on sending an out-patient letter of recommendation from a subscriber and also a home-visit ticket. Two hundred of such tickets, available for the then ensuing year, shall be issued to a committee of the town of Guildford on the payment of a sum of £50 for such year, and so on from year to year until the arrangement be terminated either by the governors or by the said committee." We have already expressed our doubts about this recommendation. It appears that the practice of seeing patients at their homes is not new in the system of this hospital. What is new is that the town, in its Diamond Jubilee gratitude, is to give £50 to the infirmary for 200 tickets. This bargain is not very complimentary either to the medical profession or to the Diamond Jubilee. Hospitals are meant for the treatment of in-patients. To say that people to the number of 200 who are too ill to be accommodated in the hospital are to be treated at home by the junior house surgeon for the consideration of £50 is not to offer them hospital advantages. Hospitals should restrict themselves to their own work and leave outside work to be done by arrangement with medical men acting privately or through a provident dispensary. One speaker defended the arrangement on the ground that cottage hospitals were being multiplied so much as to endanger the support of the county hospital, and that the managers must do more to draw closer the connexion which had always existed between the town and the hospital. We observe, with some surprise, that the medical speakers supported the proposal. Dr. Russell thought that 10*s*. would represent the market price of the visits and medicines to each patient. He

Hosted by Google

it remembered that they are ill—patients too ill to attend the hospital—presumably, therefore, in need of much attention and skill. Surely Dr. Russell does not properly hold up either the value of medical service or the standard of attention due to those very ill.

THE LATE MR. L. P. CASELLA.

MR. LOUIS PASCAL CASELLA, who died at Highgate on April 23rd, aged eighty-six years, will long be remembered as the author of many important improvements in scientific apparatus of various kinds, especially in thermometers and in the instruments used by meteorologists. In particular he did much for the clinical thermometer. Sir William Aitken, of the Army Medical School, has perhaps the best claim to be regarded as the pioneer of medical thermometry in this country, and Mr. Casella has the credit of being the first to construct a registering clinical thermometer. The present serviceable pattern was slowly developed. Many middle-aged practitioners will recollect the time when there was no self-registering index and when the stem was about ten inches long, as it was necessary to take the reading before the instrument was removed from the axilla. Mr. Casella belonged to an Italian family, but he was born in Scotland and came to London when a youth.

THE PROFESSION OF MEDICINE A DEPARTMENT OF THE STATE.

OUR Australian Correspondent writes: — The retiring president of the Queensland Branch of the British Medical Association, the Hon. C. F. Marks, M.D.R.U.I., proposed in his address that the medical care of the people should be part of a Public Health Department of the State. He suggested that a medical service for the whole colony be established, modelled somewhat on the lines of the Army Medical Service. The country should be divided into suitable districts having a senior and two junior men to each, with relieving officers and inspectors; salaries to begin at not less than £300 a year, and promotion to be by years of service or for distinguished service on ballot of all the medical officers. Dr. Marks assumes that there are about two hundred practitioners in Queensland, with, roughly, an average income of £1000 a year, and the population is about 500,000. A sum of 8*s*. per head of population raised by Government taxation would give ample funds for the scheme, allowing for fair superannuation allowances. Such a scheme, he maintained, was the only remedy for the present abuses of lodges, dispensaries, and hospitals. At the annual conference of the Political Labour League of New South Wales on Jan. 26th it was moved and carried, "That the care of the public health being among the first duties of the State, the practice of medicine should be a national service, the country to be divided into medical districts in charge of Government medical officers, whose services shall be absolutely free." The proposal simply charmed a large proportion of the conference.

A COURSE of lectures on Diseases of Tropical Climates will be delivered by Dr. Patrick Manson in the medical school of St. George's Hospital on Tuesday, May 18th, and every succeeding Friday and Tuesday till July 23rd, at 5 P.M. The course is intended for medical men intending to practise in the tropics or in Eastern Asia, and as far as practicable will be illustrated by living specimens and by demonstrations of parasitic organisms associated with these diseases. The fee for the course will be three guineas, and application should be made to Dr. Isambard Owen, Dean of the Medical School, St. George's Hospital, S.W., from whom cards of admission may be obtained.

ON Wednesday morning seven more nurses, sent out under the auspices of the committee of the *Daily Chronicle* Fund for the Greek Wounded, left Charing-cross Station, *en route* for Athens.

PROFESSOR GEORGE HARE PHILIPSON, M.A., M.D.Cantab., D.C.L., has been re-appointed the representative of the University of Durham on the General Medical Council.

WE regret to announce the death of Dr. James Andrew, consulting physician to St. Bartholomew's Hospital, which took place on April 21st. Next week we shall publish a full obituary notice of his career.

THE Ingleby Lectures will be delivered at Mason College, Birmingham, by Professor Bennett May on May 19th and 26th, the subject being the Operative Treatment of Cancer of the Breast.

WE understand that Mr. Owen, the senior surgeon to St. Mary's Hospital, will be a candidate for a seat on the Council of the Royal College of Surgeons of England at the forthcoming election in July. The last representative that St. Mary's Hospital had upon the Council was Mr. Haynes Walton, who was elected in 1873.

Pharmacology and Therapeutics.

EUCAINE HYDROCHLORATE.

THIS remedy continues to attract attention, but further experience tends greatly to modify the enthusiastic records of early days. Professor Hobday of the Royal Veterinary College, London, has lately published the results[1] of the use of eucaine as a local anæsthetic. He says that the use of cocaine for operations upon the dog and cat must be attended with the greatest caution, as the toxic doses are very small. The newer remedy has been employed by him in some forty cases, some of them being specially favourable for making a comparison between the action of eucaine and cocaine. His results confirm the opinion that the toxic dose of eucaine is somewhat larger than that of cocaine and, at the same time, that for operations on the cornea eucaine compares very favourably with cocaine, although anæsthesia is not produced quite so rapidly; but for its local anæsthetic effects when injected subcutaneously or applied locally to places other than the eye, the results obtained in the horse, dog, and cat have not by any means come up to the results obtained with cocaine. It has been found, however, that a mixture of cocaine and eucaine dissolved in water possesses the better anæsthetic properties of the cocaine solution, and can be tolerated in larger doses than cocaine alone; and this is undoubtedly of advantage when removing large tumours from animals in which the toxic dose is so small. The solution of cocaine and eucaine recommended consists of half a grain of each to the drachm of water. With regard to the amount that can be used subcutaneously with safety, Professor Hobday considers that in the case of the cat and dog about one-fifth of a grain to each pound of body weight should not be exceeded.

THE TREATMENT OF ASCITES BY THE INJECTION OF OXYGEN INTO THE PERITONEUM.

M. Tessier last year recorded a case of ascites at the Lyons Société Nationale de Médecine, which had been successfully treated by Potain's method of abdominal puncture followed by injections of oxygen into the peritoneum. The case was one of ascites and generalised œdema, which probably depended upon cirrhosis of the liver. After the first tapping fourteen pints were withdrawn, but the fluid rapidly collected again. A second puncture was then made, and followed by the injection of 1300 cubic centimetres of oxygen. The operation was not painful and there was no rise of temperature. The abdominal circumference diminished from 128 to 102 centimetres, and the œdema of the lower limbs disappeared

[1] Journal of Comparative Pathology and Therapeutics, March, 1897.

Hosted by Google

very rapidly. When the case was reported the abdomen still measured 102 centimetres, and was quite resonant all over.

ANALGEN.

Analgen is the name given to a drug which for the most part has a similar composition and action to phenacetin. It is, however, said to have less toxic action owing to the fact that quinoline exists in its composition instead of phenol. As an antipyretic it is said to act slowly but surely, and so any sudden drop of temperature which might be attended with collapse is avoided. There is one important fact that is pointed out with regard to its action and that is that it is liable to produce periodical discolouration of the urine. This discolouration is said to be due to the combination of decomposition products of the analgen with the uric acid present in the urine. It is, however, stated that by giving bicarbonate of soda with the analgen this discolouration is avoided.

THE TREATMENT OF HÆMOPTYSIS.

The direct effect of drugs in arresting the hæmorrhage which occurs in cases of pulmonary tuberculosis is very difficult to estimate with any amount of accuracy. The majority of cases tend to become spontaneously arrested, and any drug which has been given previously is apt to get the credit of stopping the bleeding. Dr. Deguy believes strongly in the value of full doses of gallic acid in this condition, and he gives this drug in doses of from four to fifteen grains in the form of powders, pills, or solutions. In cases where the hæmorrhage is very severe he associates the gallic acid with ergotin thus: ℞. Gallic acid, thirty grains; ergotin, fifteen grains; make into twenty pills, of which five or more are to be taken each day. Others, however, do not put much faith in the action of these and other astringents of the same class, and it is difficult to see how such drugs can have any definite action on the bleeding vessels, the walls of which are generally severely diseased. The application of an ice bag is also another method which is believed by some to be efficacious, while others will have nothing to do with it. It is, again, difficult to see how this method of treatment can be of any direct use except by mechanically assisting to keep the patient quiet. One of the most effective methods of treating an ordinary case of hæmoptysis consists in giving a small hypodermic injection of morphia, which generally results in arrest of the hæmorrhage and the patient is at the same time mentally soothed.

THE TREATMENT OF EXOPHTHALMIC GOITRE.

M. Viguard showed a patient at the Lyons Medical Society who had suffered from exophthalmic goitre for three years, and had been treated by section of the cervical sympathetic. The case had been a very marked one in some respects; the exophthalmos and tremor were very marked—the pulse-rate was 108 per minute, but there was no goitre. At the end of January the cervical sympathetic was divided, and the superior ganglion extirpated. Considerable amelioration followed, especially seen in the diminished tremor, but the pulse-rate was not much modified.

M. Huchard prescribes bromhydrate of quinine and extract of ergot in the form of pills in those cases where vaso-motor symptoms are prominent. He has also given antipyrin with good results. Germain Sée has recommended the tincture of veratrum viride in small doses in this disease.

PHENOCOLL IN MALARIA.

Dr. Lavrinovich has found that hydrochlorate of phenocoll will sometimes succeed in controlling obstinate cases of malaria which resist the action of quinine. He prescribes about six grains three times daily, and has not noticed any unpleasant by-effects.

UNIVERSITY OF EDINBURGH.—The following is a selection from the degrees conferred at the Graduation Ceremonial, held on April 10th. Honorary Degree of Doctor of Laws:—Professor James Dewar, M.A., LL.D., F.R.S., University of Cambridge and Royal Institution, London; Emeritus Professor Sir Douglas Maclagan, M.D., &c.; and John Wyllie, M.D. Degree of Bachelor of Medicine and Master of Surgery:—Alexander Moir Rattray, James Trevor Williams. Degree of Bachelor of Science in the department of Public Health:—Patrick Hunter Gillies, M.B., C.M.; Rhodes Haygarth, M.B., C.M.; Herman Schmitz, M.D. (*in absentiâ*).

The Lancet Special Commission

ON THE

METROPOLITAN WATER-SUPPLY.

X.[1]

EAST LONDON WATERWORKS COMPANY.

History.

IN THE LANCET of April 24th (p. 1162) a description was given of certain water businesses which have ceased to exist, and it was mentioned that more than one of such undertakings in the East-end had been absorbed by the East London Waterworks Company. The earliest businesses which were carried on in the East-end of London were those of the New River Company, the Shadwell Company, and the West Ham Company, but the supply was so inadequate that many persons were obliged to get water "by any casual means or circumstances placed within their power."

The Shadwell Waterworks.—The Shadwell works were originated by Thomas Neale, who hired land for the purpose from the Dean of St. Paul's. A four-horse engine was at first used to pump the water, but in the year 1679 the works were enlarged and a second four-horse engine was added to that already in use. In the year 1687 Mr. Neale obtained a charter for carrying on his business and formed a company consisting of thirty-six shares, some of which he was able to sell at a good price. In the year 1691 the shareholders became a body corporate by letters patent. For a long time horses only were used for pumping the water. It was not until the year 1750 that a steam engine was put up. This engine was found to be incapable of doing the work which was necessary, but no further improvement was made until the year 1774, when one of Boulton and Watts's engines was erected. This engine was capable of raising 54 000 gallons of water an hour and was found not only to save expense in working but to increase very much the power of the Company to supply water. The districts supplied by the Company included the space from the Tower of London on the west to Limehouse on the east, and from Whitechapel on the north to the River Thames on the south.

The West Ham Waterworks.—A water business was started in 1745 to supply the lower part of Whitechapel, Stepney, Bethnal-green, and the villages of Bow, Stratford, and Bromley. The water was pumped by a steam engine and by a water-wheel, and there was a reservoir at Mile-end. This property was divided into four shares, and the works and those at Shadwell were bought by the London Dock Company in the year 1807.

The East London Waterworks Company was established in 1808 and purchased the Shadwell and West Ham works. The Company chose Old Ford as the best place for a pumping station and thirty acres on the banks of the Lea were bought. Four reservoirs were constructed having a total area of eleven acres. The two largest of these were situated on the east side of the Lea. The bottom of these reservoirs was made at the level of the bed of the river and their depth was 10 ft. The smaller reservoirs were 15 ft. 6 in. in depth and were situated on the west side of the river. The level of the bottoms of these was 5 ft. 6 in. lower than that of the others, and was 15 ft. below the surface of the water at half-tide, and their surface level was between that of the spring and neap tides. The water from the Lea passed into the reservoirs through six openings which had a total width of 42 ft., but differed in depth. Two of them were 4 ft. 6 in., three others were 4 ft., and was one 3 ft. 6 in. During the spring tides the water ran into the reservoirs for about four hours each tide. During the neap tides the water flowed in for about two hours. The reservoirs had sufficient storage capacity for a week's supply. It was usual to allow the water to remain two or three days in the reservoirs before it was used so that it might "deposit its feculence and become clear." The

[1] Nos. I., II., III., IV., V., VI., VII., VIII., and IX. were published in THE LANCET of Feb. 20th and 27th, March 6th, 13th, 20th, and 27th, April 3rd, 17th, and 24th, 1897, respectively.

Hosted by Google

reservoirs were arranged in such a way that the water from any one of them could be drawn off separately. The mud which accumulated at the bed of the reservoirs was removed from time to time. When this was done as much water as possible was allowed to flow out at the time of the lowest neap tides. The water which still remained in the reservoir—a depth of about 18 in.—was pumped out by the engines. An aqueduct which passed under the Lea connected the reservoirs. The Company had another reservoir at Mile-end near the Regent's Canal Bridge. This was situated 60 ft. above the level of the River Lea and was capable of holding sufficient water to supply 6000 houses. The station at Old Ford was a little over three miles from the Thames. The Act of Incorporation of the Company provided that the whole supply of water should come from the Lea when the water flowed up during the tides and the mills were not working. It happened that, as the sluices belonging to the mills on the Lea were not always opened to the same extent, the time at which the water reached the reservoirs varied; but, as a rule, it was found that the time of high tide at Old Ford was an hour later than it was at the point of junction of the Lea and the Thames. It was stated also that the level of the surface of the Thames was 13 ft. lower than that of the Lea. At the mouth of the Lea the rise of the tide was 18 ft.; at the waterworks it was only 5 ft. From these observations it was concluded that the water of the Lea was pent back during the rise of the tide in the Thames, and that as four hours elapsed before water flowed into the reservoirs it was the water which had collected in the Lea between the Thames and the reservoirs which passed the inlet to the reservoirs and filled them. The rate of the flow of the Lea towards the Thames was about two miles an hour, but the water returned at a rate of about one mile an hour, and the ebb tide opposite the works lasted about three hours. It was therefore concluded that only the Lea water was taken into the reservoirs and that the water taken by the Company contained no Thames water. In the year 1829 the Company obtained an Act to enable them to make a canal to convey water from a place near the Lea Bridge Mills and to construct a reservoir for receiving it near their works. In 1835 there were two engines of 40 horse-power, another of 70, and two others of 90 horse-power, which could be worked against a head of 108 ft. A water-wheel at Stratford was also used. The wheel worked generally for about twelve hours a day, and occasionally for a longer time. There was at this time an engine at Shadwell which pumped water from the Thames. The number of customers of the Company was about 45,000, and the district extended from Old Ford to Lower Clapton. From thence the boundary ran to Sun-street, Bishopsgate-street, Mansell-street, and Goodman's-fields, and southwards to the Thames at a point between the London and St. Catherine's Docks. The water was distributed through between 200 and 300 miles of pipes varying in size from 36 in. to 6 in. in diameter. The area supplied extended to a distance of three miles from the central works and the engines worked against a head of 120 ft. of water. At this time the height of the water-service varied from 6 ft. or 8 ft. above the level of the Company's works. Some houses, however, were served as high as 30 ft., but the Secretary of the Company urged that as they neither professed to give high service nor made any charge for it the difference in the height could not be reasonably a source of dissatisfaction to the tenants. The amount of water supplied daily at this period was 170,000 gallons. In the year 1828 the quantity of water pumped daily by the East London Company was 6,512,292 gallons. At this time the engines were able to pump over 8,000,000 gallons, and a new engine was being put up to increase the pumping capacity by over 3,000,000 gallons. The number of houses supplied was about 42,000. In the year 1815 the Company made an arrangement with the New River Company by which each withdrew from a part of its area of supply, and each Company authorised the other to resume its freedom of action in case of neglect or refusal on the part of the other to carry on the business there. By this arrangement no exclusive right was retained. At this time the London Bridge and the Lea Bridge Waterworks were still in the field. In 1820 the Company bought the Hackney Waterworks and Lea Bridge Mills, and obtained an Act of Parliament to enable them to remove their intake from Old Ford to Lea Bridge, from which point the water was brought down by a conduit and stored at the reservoir at Old Ford and pumped thence for the supply of the district. In 1852 an Act was obtained to allow the Company to make a new cut in connexion with the Lea for the purpose of improving the quality of the water, to construct reservoirs at Walthamstow, filter beds at Lea Bridge, and to make an intercepting cut on the west side of the Lea from Tottenham to a point below Ponders End to prevent polluted water from entering the river above the intake. In 1867 an Act was obtained to allow the Company to make a covered reservoir at Finsbury Park, and to make works at Sunbury for the supply of Thames water. By this Act the Company were allowed to take a quantity not exceeding 10,000,000 gallons of water daily from the Thames. In 1867 another Act was passed to allow the Company to increase the number of reservoirs at Walthamstow and filter beds at Lea Bridge, and they were compelled to discontinue the use of, and to fill up, the reservoirs at Old Ford, and to leave off using the open canal which connected the reservoirs with the works at Lea Bridge. This alteration immediately followed the cholera visitation of 1866—a visitation of which the geographical limits were very much those of the area supplied from the reservoir at Old Ford.[2] In the year 1886 an Act was passed which, among other things, authorised the Company to sink wells and to make works with the object of intercepting sewage and preventing it from getting into the river above their intake. In the year 1892 the works at Old Ford were finally given up.

A new reservoir has just been completed, another will be ready for use in the course of a few weeks, and new wells are being sunk. The Company are this session promoting a Bill to authorise them to make more new reservoirs.

THE HOSPITAL REFORM ASSOCIATION.

A MEETING of the Hospital Reform Association was held in Birmingham at the Grand Hotel on Wednesday afternoon, April 21st.

Mr. JORDAN LLOYD, who presided, in opening the proceedings said the meeting was called to create interest in questions which were thought by many to be ripe for discussion, to demand careful inquiry, and for settlement. This matter of hospital reform had been discussed over and over again; it had agitated the lay and the medical mind for many years, and in Birmingham a few years ago a committee sat for some days, and arrived at a series of conclusions which were almost practically identical with the objects of that association. The movement was not a professional one, and he was not sure that its initiation came from the medical profession; it certainly was not confined to the profession. It was a question which concerned the public equally with the profession, and it concerned the philanthropic part of the public as much as any other. The first object of the association was to prevent the abuse of hospitals, infirmaries, and dispensaries. There seemed to be a large number of persons who questioned whether there was such a thing as abuse of these institutions; but no impartial man who looked the facts of the position in the face without prejudice could fail to see that abuse. He thought that abuse was dominant in many of the hospitals of the kingdom. The first purpose of a hospital was to supply the sick with that medical attention which their cases demanded and which they were unable to obtain by reason either of their poverty or of the severity or peculiarity of their malady. Hospitals were not cheap "doctor-shops"; they were not for the distribution of cheap physic; they were not matters of mere public convenience. Another reason for the existence of hospitals—and it was a real reason—was the training of medical men. They were fortunate in Birmingham in regard to their Poor-law administration, and he felt proud of the fact that in that city the very poor people, he would not say were doctored, but had potentialities for being doctored a great deal better than that of the average middle-class. Therefore, what was constantly being said in Birmingham—namely, that the first object of hospitals was the doctoring of the poor was all moonshine. They were delighted to see the poor there, and to do the best they could for them; but the poor knew very well that there were other systems of medical relief which offered them quite as good advantages, and better

[2] "The area of intense cholera of 1866," according to Sir John Simon, "was almost exactly the area of this particular water-supply, nearly, if not absolutely, filling it, and scarcely, if at all, passing beyond it."

Hosted by Google

in many respects than were offered to them by the hospitals. That the question of abuse could be dealt with, and would be dealt with, in a way satisfactory both to the public and to the medical profession he was quite confident. The second object of the association was to promote the establishment of central hospital boards in London and other large towns. He had thought over this question for many years, and he was absolutely certain that there were more economical ways of administering hospitals than were now practised. If the whole of the hospitals in Birmingham were administered by some central board or committee the administration would be very much cheaper. That this was done was due to the existence of an absurd jealousy on the part of the hospitals one against another. There ought to be no jealousy in the doing of common work like that of hospitals. The formation of a central board would also assist in preventing abuse. The third object of the association was to provide properly regulated provident dispensaries. One of the suggestions made by the association was that the number of cases seen by one medical man in one day should not exceed twenty. That suggestion he thought utterly impracticable. At the Queen's Hospital one of their officers limited his number to twenty-five, but he (the chairman) had not ventured to adopt any such limit, because it was possible that if he did so he should see twenty of the most trivial cases. Those who were able to push their way to the front and those who lived nearest would get the first attention, and the more trivial the malady the earlier, probably, the patient would be there. He would not allow that every person who received an injury, no matter how serious, was entitled to go to a hospital for a first opinion. Whether persons in such circumstances got the best opinion by going to a hospital was a question he would rather not touch upon, but hospitals were only bricks and mortar, and the skill of a hospital depended upon the skill of its staff. Mr. Jordan Lloyd then moved the following: "That this meeting of the medical profession practising in Birmingham and the district is of opinion that the question of hospital reform should be dealt with without further delay by the lay managers and acting staffs of our various hospitals and dispensaries, and thinks that the recommendations issued by the Hospital Reform Association for the better regulation of the out-patient and casualty departments are worthy of their close consideration."

Mr. M. HALLWRIGHT seconded, and Mr. E. CHESSHIRE supported the motion.

Dr. KIRBY moved as an amendment, that selected representatives of the general practitioners should be added to the committee to consider the subject.

Mr. A. OAKES seconded the amendment.

The CHAIRMAN said he could not accept Dr. Kirby's suggestion as an amendment, because the reference to the central board was one of the objects of the association, and at present it was not defined how that board should be constituted. He had no doubt the claims of the general practitioners to representation would be considered.

Dr. ISAMBARD OWEN said he could not agree with the chairman that the principle of limiting the number of out-patients was impracticable. So far from being impracticable it had been carried on at St. George's Hospital with complete success for over thirty years, and it was a principle which everyone connected with that hospital would be sorry to see altered. Two objects were aimed at: in the first place the benefits of the hospital should go only to those whose poverty rendered them worthy objects of charity, and, secondly, that the hospital charity should go to the severest cases that applied. The out-patients were seen every day, first of all by the resident medical officer, who examined them from the point of view of the severity of their cases, and then from the point of view of their social position. Assuming the applicants to be fit objects for charity, he picked out fifteen medical and fifteen surgical cases, apparently the most serious, for treatment that day, and the other applicants might, if they chose, apply another day. If, however, any of those cases were so urgent that the postponement of treatment would involve any serious risk, the resident medical officer, at his discretion, was empowered to prescribe treatment for a single day, but it was very rare that it was found necessary to exercise that power. At St. George's Hospital, too, there was a system of inquiry by the officers which answered extremely well. There were no out-door inquiry officers, but the resident medical officer made the necessary inquiries of the patient, and he was rarely mistaken in the conclusion he arrived at. If he was doubtful as to the social position of the patient the latter was sent to the secretary, and if the latter had any doubt treatment for the time being was given and the case referred to the Charity Organisation Society. If that society reported unfavourably further treatment was invariably refused. In Birmingham, with its much more complete municipal organisation, he should think there would be little difficulty in organising a central board of inquiry which would be very effective. The system he had alluded to had worked remarkably well at St. George's Hospital during the eleven years he had had experience of it.

Dr. AYSHFORD said he believed that a man who was willing to work hard among the poor could make a good living—in fact, better than he could among the richer classes; but the competition of the hospitals pressed very hardly upon the general practitioner.

The resolution was carried unanimously.

Mr. GARRETT HORDER said that the association, though only six months old, had made some impression upon the hospital world. There had been a distinct reform movement in one of the London hospitals, in which the out-patients and casualty cases numbered 180,000 or 190,000 a year. Birmingham wanted hospital reform very badly indeed. The association proposed to hold the next meeting either in Liverpool or in Manchester, both of which towns were hotbeds of hospital abuse.

The following gentlemen were appointed to form a committee to deal with the subject of hospital reform: Mr. Jordan Lloyd, F.R.C.S. Eng. (chairman), Mr. Edwin Chesshire, F.R.C.S. Eng., Mr. J. T. J. Morrison, M.A., M.B. Cantab., F.R.C.S. Eng., Mr. G. R. Ayshford, M.B., C.M. Edin., Mr. Gordon Nicholls, L.R.C.P. Edin. (honorary secretary), Mr. M. Hallwright, M.R.C.S. Eng., Mr. L. Rose, M.B. Edin., Mr. E. D. Kirby, M.D. Edin., Mr. Arthur Oakes, M.R.C.S. Eng., and Mr. Charles S. Johnston, M.R.C.S. Eng.

THE GRECO-TURKISH WAR.

THE news—so dramatic in its effect and so disastrous to the Greek cause—cannot be regarded as a surprise; the surprise would have been if the reverse had happened and Greece had crumpled up the military power of Turkey. It has not been one of those cases in which educated and thoughtful people were wise after the fact, for there were comparatively few persons, especially among officers of the army, in this country who entertained much doubt on the subject. The difference in population of Turkey and Greece and in the military strength of the two countries, the numerical superiority of the Turkish army, the strength of its artillery arm, the character of its rifled weapons, its experience in military training and in the field, were all factors that had to be taken into account, and they left little room for difference of opinion among military experts. Since the Greek War of Independence the art and science of warfare have been revolutionised. As far as the published accounts of the history of the present war are concerned they gave, no doubt, a meagre, conflicting, and confusing description of the events that were taking place, but there is no longer room for doubt. Edhem Pasha's army has pierced the centre of the Greek frontier defence and proved victorious on its left and then on its right, and apparently secured itself against any serious flank attack. Thessaly, which Greece gained by treaty in 1881, she has lost by conquest in 1897, and the country now lies open to the advancing Turkish army. The territory beyond is historical, and the names of Pharsalia and Thermopylæ recall to mind the studies of school life and the great events of which they were the theatre in times long past. When we said last week that the Turks were apparently masters of the situation we confess that we did not realise, however, that the end was so near and that a few hours were to be crowded with such dramatic results. Turning to the conduct of Turkish troops in this war, we are bound to say that, altogether apart from their acknowledged bravery and fortitude in the field, there seems to be a general consensus of opinion that the Turks have conducted themselves admirably in the present campaign and with great moderation and excellent discipline; there have been no cruel and wholesale massacres of the inhabitants of towns and villages, and the dead and

Hosted by Google

wounded have been treated with a respect which has not usually hitherto characterised a Turkish force. On this occasion the Turks seem as if they had forsaken an article and practice of their religion, which recalls some of the wars recorded in Old Testament history, and to have taken a step forward in the conduct of civilised warfare. This should be recognised and placed to their credit and that of their able and seemingly humane leader, Edhem Pasha. Still, from the difficult nature of the country, from the amount of severe fighting which has taken place, and the rapid retreats that have had to be executed, we fear that the sufferings of the wounded and of the fugitive families must have been very great. The accounts that have reached us of the losses in the several engagements have represented these as so small that either the fighting could not have been so severe as described or the estimated losses have been greatly understated. The fact, however, is that these are unknown; there are no statistics, not even approximate statistics, and it is curious how little we have yet learned of the state of the military hospitals of the belligerent forces, of the number of wounded they contain, or of the methods of ambulance transport adopted. All this has still to be recorded, and the medical history of the campaign can only be written when it has terminated. It is fully recognised that the Greeks have fought with gallantry and held and defended their posts with brave tenacity of purpose. Towards the last, and after their defeat at Mati, when they saw that they were being out-manœuvred and surrounded and that the position was no longer defensible and had to be evacuated, it was only natural that some panic should ensue and precipitate flight. The latest accounts, however, give a terrible picture of the scene presented by the retreat of the demoralised and panic-stricken army. The line the Greeks have now taken up at Pharsalia and beyond is supposed to be capable of being far better defended than those they have relinquished, but we fear that at best a continuance of the warfare will only delay the seemingly inevitable end. As we said last week, there is ample room for the provision of medical, surgical, and philanthropic aid to the sick and wounded of both sides, but especially for the side of the Greeks. Switzerland is sending an ambulance corps with nine surgeons to the seat of war. The ambulance hospital and corps organised by the Imperial Ottoman Bank, and under the medical charge of Dr. Lardij, has probably reached Elassona ere this, and several nurses are leaving this country for the seat of war in addition to those who have already proceeded there.

THE NEW WATER-SUPPLY AT WORTHING.

FORMAL OPENING OF THE WORKS.

THOSE who attended the inaugural ceremony at the New Waterworks of Worthing in the brilliantly auspicious weather of Monday last must have been struck by the fact that the inhabitants of Worthing were keenly alive to the importance of the event. The picturesque town was prettily decorated and there was hardly a single householder who did not share in the enlivenment of the proceedings by displaying a profusion of coloured bunting on his house suitable to such an occasion. Nor were the town councillors behind in marking the importance of the occasion, and the Mayor is to be congratulated on arranging an attractive programme and adding brilliance to the ceremony by the excellent display which was provided in the furnishing of escorts, guards of honour, &c., a display notably enhanced by the presence in the demonstration of the lifeboat and fire brigades and a detachment of coastguards. His Royal Highness the Duke of Cambridge, escorted by General Bateson, arrived punctually at the time announced (11.45 A.M.) at Worthing Station, where he was received by the Mayor and Councillors. After an address couched in terms appreciative of His Royal Highness's visit the company proceeded in carriages to the site of the new works, which were inspected with considerable interest. The Duke started the pumping engines by giving a few turns to the steam valve admitting steam into the cylinders. The usual naming ceremony was then performed, the Duke calling one engine Victoria and the other Cambridge. Mr Mansergh, jun., son of the engineer who designed the works, then presented an interesting statement of their history and construction.

It was in 1893 that the Corporation of Worthing resolved that new works should be constructed and that the source of supply should be beyond the possibility of contamination. Subsequently Mr. Mansergh was instructed to prepare a scheme, and after consultation with several leading geological experts the present site was chosen. In the meantime, as was pointed out in THE LANCET of June 9th, 1894, a pure and abundant temporary supply of water was placed most generously, unreservedly, and in a time of the utmost need, at the disposal of the authorities by Mr. Edward Harrison, with permission to use his property at Broadwater as freely as occasion demanded. It is pleasing to learn that this magnaminious action was recently appreciated in a practical manner by the authorities at Worthing, who presented him with a service of plate in acknowledgment of the real and important work of rescue which Mr. Harrison had so nobly and unstintedly done. The new well, which is situated under the western end of the engine house, is 115 ft. deep from the ground surface. It is sunk 60 ft. into loamy clay and sand and 50 ft. of solid chalk. For 80 ft. downwards the boring is 12 ft. in diameter, while lower it is 12 ft. The upper sides of the well to the extent of 33 ft. are lined with eighteen inches of brickwork in cement, and the lower portion with cast iron cylinders. Water was found as soon as the chalk was reached, and by the time the well was sunk to its full depth the quantity yielded was about 1,000,000 gallons per day. From near the bottom of the well headings are driven in a north-westerly, easterly, and south-westerly direction for an aggregate distance of fifty yards, and are lined with brickwork. The pumping machinery consists of two horizontal compound differential condensing engines, each working a pair of pumps which lift the water into chambers under the engine-house floor, whence it is forced by two pairs of double-acting force pumps through a 16-inch rising main to the reservoir in the chalk on the Downs close by, each pair of pumps being driven by one of the engines. When working at the ordinary speed of twelve strokes a minute each will raise 1000 gallons per minute from the bottom of the well to the adjacent reservoir. The reservoir on the Downs is capable of holding 2,000,000 gallons and is circular in plan and 25 ft. deep; it is constructed with concrete walls and floor, and lined throughout with asphalt, the asphalt on the walls being protected by brickwork. The top water level is 190 ft. above ordnance datum, or about 80 ft. higher than the old water tower in the town. The distance of the reservoir is about two miles north from Worthing. A cast iron gravitation main, 14 in. in diameter, is laid from the reservoir to near the railway station, and is connected by branches with all the principal distributing mains in the town and also to a trunk main which is part of the old West Worthing waterworks, which the corporation has purchased, and which supplies the west ward of the borough. The total cost of the undertaking amounts to nearly £31,000. The yield of water has been thoroughly ascertained, and it it estimated at an average of 1,500,000 gallons a day, which at 30 gallons per head per day would be sufficient for the supply of 50 000 persons. Since the resident population is about 19 000 there is an ample margin for the provision of visitors. From the results of an analysis made in THE LANCET Laboratory, and published in our columns last week, it will be seen that the water is of admirable purity and well adapted for all dietetic purposes.

It should be added that the sewerage system has been thoroughly overhauled and reconstructed. A new main sewer has been laid right through the town, and pumping plant and storage-tanks have been installed near the outfall, at the eastern extremity of the borough, for removing the contents of the sewers and for storing the sewage during the time of tide locking, and thus preventing the forcing of the sewage back into the mains, which hitherto had proved a frequent source of annoyance and trouble. The outfall itself has also been lengthened so as to carry the sewage to below low water mark and to avoid the discharge of sewage upon the beach. The discharge is allowed to take place under the best conditions for its removal by the sea without pollution of the foreshore. These improvements have cost a little over £37,000.

Hosted by Google

There was a distinguished company present at luncheon at the town hall after the opening ceremony. The Mayor (Captain A. B. S. Fraser) presided. Amongst those present were Lord Edmond Talbot, General Sir William Butler, Sir Henry Fletcher, Admiral Vansittart, the Bishop of Chichester, Colonel Tolson, Colonel Gem, Colonel Nobel Edwards, and the Mayors of Brighton, Chichester, Arundel, and Lewes. The toasts, which were commendably few and short, referred chiefly of course to the important event in the history of Worthing which had been signalised that day. The authorities have not left a single stone unturned to insure the healthiest possible conditions of the town. They have spent a large sum of money, probably amounting to over £100,000; but it would have been impossible to have devoted such a sum to a better purpose. It is an outlay which now enables them with every right to say that the sanitary provisions of the town of Worthing in regard to water-supply and sewage disposal are second to none in any other health and seaside resort in the kingdom. The whole incident has proved an excellent object lesson in the first principles of sanitation, and though the past has been a bitter experience there is no reason now why the future should not bring with it well-earned prosperity. With the ceremony performed by His Royal Highness the Duke of Cambridge on Monday last the sanitary difficulties and troubles of Worthing, we may confidently hope, have ceased.

THE SANITARY CONVENTION OF VENICE, 1897.

No. I.

THE Sanitary Convention which was signed at Venice in March last is the fourth of a series of International Conventions which have as their aim the control of foreign infectious diseases in such a way as to prevent their spread into neighbouring countries other than those in which they happen to prevail, and especially into Europe. For many years before any Conventions were signed there had been international gatherings which had been convened with the same object, but the resulting proposals were all so largely based on purely quarantine lines that Great Britain could never accept them, and not one of the Conventions was ever ratified. The last of these conferences which thus failed was held in Rome in 1885, and after this date it seems to have been understood that a successful conference must mean much more advance on the lines of English sanitary administration than the European nations had ever yet assented to.

The first of the four successful conferences was held in Venice in 1892, and after the resulting Convention had been somewhat substantially modified to meet the views of this country it was ratified and was accepted by the principal European nations. It dealt with cholera, and it went on the mistaken notion that the greatest danger to Europe was by means of the sea route. Those who held that view saw no difficulty in stopping cholera at the Suez Canal, and although they were warned by the British delegates that the land route was a much more serious danger, they contented themselves by controlling the sea route only. The Venice Convention of 1892 was, however, a document of the greatest importance for this country, because it enacted for the first time that a vessel arriving in the ports of any of the contracting countries was no longer to be judged by reason of the health of the port from which it had sailed, but by reason of the actual state of health of those on board. It is true that this great concession to British views was more complete in words than in fact, because free pratique was not to be granted at Suez, for example, unless five days had elapsed since the vessel had left the last infected port. This, however, made no difference to our traffic from Bombay, where cholera is unfortunately all but endemic, because the five days had always fully elapsed before a vessel from British India could reach the Canal; and the condition was hence assented to by this country. Another set of provisions dealt with the case of vessels reaching Suez and on board which cholera had actually occurred. Here again there was substantial advance in the direction of British views; for it was conceded that if the sick persons, together with those who had been in actual contact with them, were landed at the hospital established at Moses' Wells the vessel might after disinfection be allowed to proceed on its journey to the Mediterranean, provided the passage of the Suez Canal was effected "in quarantine," that is to say with guards on board who would prevent communication with the shores of the canal. These were, substantially, the two great points of interest in this Convention in so far as Great Britain was concerned; but the Convention dealt in detail with a number of other subjects, including regulations as to arrivals at Egyptian ports and the re-constitution of the Sanitary, Maritime, and Quarantine Council of Egypt—an international body which is responsible for the control of disease in Egypt, for the management of some of the pilgrim stations on the Red Sea, and also for regulating the traffic of the Suez Canal in so far as health and disease are in question.

But whilst the first Venice Convention was engaged in discussing the sea route, and openly ignoring the land route of cholera, that disease was slowly but surely advancing through Turkestan and towards the Russian frontier, which it soon passed, and then overspread Europe. This event led to the urgent assembly of the second successful International Sanitary Conference, which was held at Dresden in 1893, and which had for its professed object to control cholera when once it had made its way into Europe, and to prevent its diffusion from one country to another, whether across land frontiers or by way of sea and river routes. The question of control by land routes in Europe had no direct concern for this country; but that by way of the sea route was important. The result of the Conference was in this respect in the main satisfactory, for it applied the principles of the Venice Convention of 1892 to the circumstances of Europe, and it avoided, for the first time, making it compulsory for any nation who should adhere to the Convention to impose quarantine in their ports. It is true that quarantine was still permissive under the new name of "observation" for a limited period of five days, but the Convention practically accepted as an alternative the English system of merely keeping suspected persons under supervision in their own homes and of allowing the infected vessel to depart free of control as soon as the sick had been landed in hospital and certain measures of disinfection had been carried out. Great Britain ratified this second Convention after making it clear, by means of a special reservation, that she only adhered to its terms on the distinct understanding that for the purposes of British ports "observation" would never be construed into the quarantine detention of healthy people or of ships which, though they might have been infected, had been properly disinfected.

But the Venice and the Dresden Conventions only professed to deal with the control of ordinary traffic by land and by sea for the purposes of the prevention of cholera, and it was very properly admitted that one of the greatest dangers of cholera lay in the pilgrimages paid by Mohammedans to Mecca and Medina in the Hedjâz. Hence the French Government invited the principal nations of the world to assemble once more in 1894 in Paris in order to prepare a Convention for the control of the spreading of cholera by Mussulman pilgrims, whether they came from British India, the Dutch Indies, or elsewhere in Asia, or whether they started from Egypt, Algeria, Bosnia, Russia, &c., on the Mediterranean side of the Suez Canal. A very complete code was drawn up; but for us its interests centred in the measures to be taken at the departure of pilgrims for Indian ports, at the detention in the island of Camaran in the Red Sea before landing at Yeddah, and in the proposed sanitation of the towns and cities visited by the pilgrims in Arabia. This Convention again exhibited considerable progress, and, above all, it called upon Turkey to give to the quarantine station of Camaran some semblance of healthiness and decency; and to provide for the pilgrims on their journey through Arabia some proper health accommodation, and wholesome water. It also reduced the periods of quarantine detentions hitherto enforced by many days. But, it went on the assumption that Turkey, who took all the sanitary taxes of the pilgrims, would do her duty in this matter, and it failed to take proper account of the endless delays and evasions which always characterise Turkish administration. Turkey, too, declined to sign the Convention and pleaded that this country had only signed with reservations. That was true. One of our reservations was designed to relieve us from the obligation of collecting Turkish taxes for the Turkish Government, for we declined to include all those

Hosted by Google

taxes in the price of the pilgrim's ticket; another was concerned with the amount of space to be allotted to pilgrims on board pilgrim vessels; and the third reservation announced that Great Britain and British India refused to be controlled by the regulations laid down as to traffic in the Persian Gulf. The truth was that the Paris Convention absolutely abandoned, as regards the Persian Gulf, all that had been conceded by the Conventions of Venice and Dresden as to judging a vessel by reason of the health on board instead of by reason of the health of the port of departure; and this unfortunate abandonment of principle led to the Paris Convention never being issued by the French Government. It is true that the document had been signed, but it could only be ratified by this country with reservations that were regarded as of such importance that it was deemed preferable to ignore it and await a more favourable opportunity for reviewing the whole matter.

These three Conventions had been concerned with cholera, but last year plague became much the more pressing and important disease. This occurrence afforded an opportunity for a fourth International Conference—namely, the one held this year in Venice. It concerned itself with the control of plague by land and by sea, and it afforded an opportunity of once more raising questions of the ratification of the Paris Convention, which had remained a dead letter. It was under these circumstances that the International Conference recently met and brought to a successful termination labours that resulted in the signature of a fourth Convention—namely, the Sanitary Convention of Venice, 1897, the provisions of which we propose to discuss in some detail in a series of articles.

THE ROYAL ACADEMY.

THE 129th exhibition is, we think, quite up to the level of its predecessors, and if there is no very striking picture there are many above the average. The days have gone by of roped-in pictures attended by a policeman to move on the crowd, but in the present exhibition there are one or two works which will excite worthy attention.

We are glad to be able to note the absence of death-bed scenes and sick children, for the charnel-house school of painting is a thing to be deprecated. Among the works which particularly struck us was "Calypso's Isle" (39) by Mr. Herbert Draper. This artist's work is always clever, and he is quite up to his usual level. The nymph is sitting in a rock with her back towards the spectator; she is correctly drawn and modelled and the flesh tints are good. Also Mr. Draper deserves a word of praise for his sea, for he has managed to give very truly the effect of that ever-changing Mediterranean so indefinite with its blues and greens and purples dashed with red that the old dwellers by its shore were reduced to calling it wine coloured. Mr. Walter Shaw has met with his usual undeserved fate of being very badly hung, but his "Rain Squall" (311) shows his power of representing our cold, grey, northern waters; moreover, his water looks wet, an effect we do not always see in sea pieces. Mr. J. C. Dollman has a "Temptation of St. Anthony" (445). The animals are good, but we do not consider that it would take a saint to resist the young woman, for she looks unhealthy and œdematous. "Hamlet," by Mr. E. A. Abbey, is an amazing picture, barbaric to a degree and blazing with colour. The subject is the Play Scene, although the players are "off"; but the faces of the King, the Queen, of Hamlet and Ophelia, and of the rough soldier courtiers afford wonderful studies of varying expressions.

Mr. J. R. Weguelin deserves a word of praise for the anatomy of his Nymph (600), though she is hung in a bad light. But perhaps the most striking thing in the galleries is (663) "Steady the Drums and Fifes," the 57th (Die hards), drawn up under fire on the ridge of Albuera, by Lady Butler.

To the picture is appended a note from Cardinal Manning concerning the mental strain which such an act involves, and Lady Butler has certainly succeeded in catching passing emotions and fixing them on canvas. The subjects of the picture, in many cases mere children, are waiting in the midst of death, and the mental tension is evident; one child has already been struck down, and clutches in a death grip the leg of his comrade. Mr. Rudyard Kipling's Jake and Lew were heroic, but these are even more so.

To turn to the more purely medical pictures. In the first room is the charming little portrait of the late Dr. E. Ballard by his daughter (9), a reproduction of which appeared in our columns upon Jan. 30th, 1897. Mr. C. Neil Knight has (186) "A Sister of St. Vincent de Paul," representing one of these devoted woman watching by a sick bed in the dim light. Mr. Ouless sends a fine portrait of Lord Lister (296), a presentation portrait. Another presentation portrait is that of Mr. Henry Power, F.R.C.S. (551), by Miss Lucy Power, and presented by his house surgeons at St. Bartholomew's Hospital. The technique is good but we do not think that Miss Power has quite caught the likeness. In Gallery XI. are two portraits of special interest to medical men; one (999) by Mr. H. Harris Brown, of Sir William MacCormac, a good likeness and remarkable for the skilful way in which the various shades of red in the gown, the curtain, and the tablecloth are managed; the other (1028), a very quiet, subdued picture by Mr. Percy Bigland, of the President of the Royal College of Physicians—Dr. Samuel Wilks. Mr. Ralph Hedley (1062) has a well-drawn scene called "Passing the Doctor," a study of recruits being examined. With the exception of the fact that the doctor has his stethoscope at an angle at which we are sure he could not hear anything, the picture is good. In the sculpture room are a fine medal, by Mr. Alfred Gilbert (1079), for presentation at St. Bartholomew's Hospital in memory of the late Sir W. Lawrence; a bust of Sir J. B. Lawes by Mr. F. Verheyden, and another of Mr. Dudley Edginton, M.R.C.S., by Mr. Paul Montford, a design for the Huxley Memorial Medal by Miss Ruth Canton (2035), and (2055) a life-like bust of Sir Richard Quain by Mr. Thomas Brock.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Chelmsford Rural Sanitary District.—Dr. Thresh reports that during the two years in which an isolation hospital has been available for this district the number of notified cases of infectious disease has been but one half of the previous average, and he is inclined to regard this decrease as due in part to the good effect of prompt removal and isolation. An outbreak of scarlet fever occurred in Danbury during 1896 in which those attacked were attending the infants' department of the national schools. The registers were examined, and on visiting the families of certain absentees children were discovered desquamating from scarlet fever. The outbreak in question was apparently caused by the return to school of a child from one of the invaded houses. The report before us contains a table setting forth the meteorological data, together with the deaths and notifications for the district during the past year, and Dr. Thresh observes that he will be glad if any member of the district council will study this and similar tables with a view to pointing out the relationship between the weather and the prevalence of disease. It is well that the councillors should take an intelligent interest in the statistics relative to their district, and we trust that Dr. Thresh will receive the assistance for which he asks.

Withington Urban Sanitary District.—The obscure manner in which school attendance is at times responsible for the spread of infectious disease, although that influence may not be at once apparent, is well illustrated in Dr. Railton's current annual report, in which it is stated that children suffering from measles were found to have continued at school while in an infectious condition, in spite of the fact that the teachers had been especially warned to be on the alert. Dr. Railton insists on the difficulty which must always beset attempts on the part of school teachers to recognise illness amongst their pupils, and he suggests that it would be a useful precaution to have school children inspected daily by a medical man in all instances where a case of infectious disease had been recognised among the pupils, the examination to continue as long as fresh cases occurred. Obviously the ideal conditions of inspection would be found in the regular daily

Hosted by Google

inspection of schools by medical men, but, failing that, Dr. Railton's suggestion has much to commend it.

Lytham Urban Sanitary District.—In commenting upon the prevalence of scarlet fever in this district Mr. J. H. Jenkins observes that it will be impossible to prevent occasional cases from occurring until the Notification Act is universally adopted in the country. We are afraid that even when this is the case scarlet fever will not cease from troubling us, since notification is but the expression at any given time of the cases of infectious disease which are recognised; and beyond these there will, at any rate, for many years to come, be an uncertain number of anomalous, and in large part unrecognised, cases. Lytham was one of the places which first gave trial to the Hermite system of sewage treatment, but the trial has now, it appears, been discontinued, and it is proposed to discharge the untreated sewage out to sea on the ebb tide. Mr. Jenkins is not in favour of the scheme, and he points out to the council some of its disadvantages, one of which is the pollution of a bed of mussels on the foreshore. We are glad to note that in the vicinity of this district two joint hospital boards have been formed, one to provide a small-pox hospital and the other a hospital for other infectious diseases.

Thingoe Rural Sanitary District. — Dr. Scott Kilner relates in his current annual report an outbreak of measles in which some of the patients suffered almost simultaneously from an attack of scarlet fever. These instances are always worth recording, and it is well to bear them in mind in all etiological inquiries. The recognition of the coexistence of two infectious diseases in the same individual would perhaps have been made earlier than it was, had it not been for the position taken up by John Hunter that "all diseased actions are simple," and that no two diseases were capable of existing in the body simultaneously. Hunter, however, pointed out that the potentiality of one disease may be present in the body during the manifestation of another, and he gives instances of the arrested action of inoculated small-pox in the presence of an attack of measles.

Maldon Rural Sanitary District.—This district contains, it appears, within its limits some important oyster layings, and we are glad to note that the oyster merchants have been acting, at least partially, on the advice of Dr. Thresh relative to the purification of the Burnham sewage effluent. We regret, however, to note that the sewage works, although completed, have "never been systematically attended to," and that Dr. Thresh on his visits has always found "the tanks more or less foul, and the effluent not what could be considered satisfactory," which fact is much to be deplored. We gather from the Local Government Board report that the waters of the Crouch and the Roach are exceptionally well fitted, from a sanitary standpoint, for oyster culture, and that both these estuaries could easily be rendered quite above suspicion; and the oyster merchants of the district have consequently only themselves to blame if they fail to take advantage of the excellent facilities with which nature has provided them.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6226 births and 3965 deaths were registered during the week ending April 24th. The annual rate of mortality in these towns, which had been 18·6 and 17·9 per 1000 in the two preceding weeks, rose again last week to 18·8. In London the rate was 17·5 per 1000, while it averaged 19·7 in the thirty-two provincial towns. The lowest death-rates in these towns were 10·1 in Derby, 11·2 in Croydon, 11·3 in Gateshead, and 12·5 in Brighton; the highest rates were 24·7 in Liverpool, 27·9 in Salford, 28·8 in Manchester, and 36·1 in Bolton. The 3965 deaths in these towns included 367 which were referred to the principal zymotic diseases, against 338 and 335 in the two preceding weeks; of these, 109 resulted from whooping-cough, 101 from measles, 57 from diphtheria, 40 from diarrhœa, 31 from scarlet fever, and 29 from "fever" (principally enteric). No death from any of these diseases was recorded in Preston; in the other towns they caused the lowest rates in Swansea, Derby, Hull, and Gateshead, and the highest rates in Burnley, Manchester, Salford, and Bolton. The greatest mortality from measles occurred in Newcastle-upon-Tyne, Burnley, Manchester, Salford, and Bolton; and from whooping-cough in Portsmouth, Plymouth, Salford, and Blackburn. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 57 deaths from diphtheria included 40 in London, and 2 each in Birmingham, Liverpool, Salford, and Leeds. No fatal case of small-pox was registered last week in any of the thirty-three large towns. There were 7 cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, the 24th ult., against 17, 16, and 11 at the end of the three preceding weeks; no new cases were admitted during the week. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2442, against 2512, 2449, and 2406 on the three preceding Saturdays; 269 new cases were admitted during the week, against 219, 224, and 216 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 271 and 273 in the two preceding weeks, further rose last week to 289, but were 95 below the corrected average. The causes of 59, or 1·5 per cent., of the deaths in the thirty-three towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Cardiff, Bradford, Newcastle-upon-Tyne, and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Liverpool, Preston, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·6 and 22·3 per 1000 in the two preceding weeks, rose again to 22·6 during the week ending April 24th, and exceeded by 3·8 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14·4 in Greenock and 18·1 in Aberdeen to 29·0 in Perth and 29·2 in Edinburgh. The 673 deaths in these towns included 41 which were referred to whooping-cough, 39 to measles, 11 to diarrhœa, 5 to scarlet fever, 4 to "fever," and 2 to diphtheria. In all, 102 deaths resulted from these principal zymotic diseases, against 95 and 107 in the two preceding weeks. These 102 deaths were equal to an annual rate of 3·4 per 1000, which was 1·7 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 38 and 39 in the two preceding weeks, further rose to 41 last week, of which 23 occurred in Glasgow and 13 in Edinburgh. The 39 deaths referred to measles corresponded with the number recorded in the preceding week, and included 23 in Edinburgh and 14 in Glasgow. The fatal cases of scarlet fever, which had been 3 and 4 in the two preceding weeks, further rose to 5 last week, of which 3 occurred in Edinburgh. The 4 deaths referred to different forms of "fever" showed a decline of 3 from the number in the preceding week, and included 2 in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 153 and 154 in the two preceding weeks, further rose to 165 last week, and exceeded by 56 the number in the corresponding period of last year. The causes of 46, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 38·5 to 28·2 per 1000, rose again to 34·6 during the week ending April 24th. During the past three weeks of the current quarter the death-rate in the city has averaged 32·9 per 1000, the rate during the same period being 17·2 in London and 27·3 in Edinburgh. The 232 deaths registered in Dublin during the week under notice showed an increase of 43 upon the number in the preceding week, and included 41 which were referred to the principal zymotic diseases, against numbers declining from 74 to 36 in the five preceding weeks; of these, 19 resulted from measles, 14 from whooping-cough, 4 from diarrhœa, 2 from "fever," 1 from diphtheria, and 1 from scarlet fever. These 41 deaths were equal to an annual rate of 6·1 per 1000, the zymotic death-rate during the same period being 1·6 in London and 7·6 in Edinburgh. The fatal cases of measles, which had declined from 46 to 15 in the five preceding weeks, rose again to 19 last week.

Hosted by Google

The deaths referred to whooping-cough, which had been 9 and 14 in the two preceding weeks, were again 14 last week. The 2 deaths from "fever" also corresponded with the number in the preceding week, while the mortality from scarlet fever and from diphtheria showed a decline. The 232 deaths in Dublin last week included 45 of infants under one year of age and 47 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed an increase upon those recorded in the preceding week. Six inquest cases and 4 deaths from violence were registered; and 70, or nearly a third, of the deaths occurred in public institutions. The causes of 20, or nearly 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-LIEUTENANT-COLONEL CHRISTOPHER W. M. KEYS M.D., to be Brigade-Surgeon-Lieutenant-Colonel, vice T. O'Reilly, retired.

Surgeon-Lieutenants Gaine and Phillips have joined at Woolwich.

INDIA AND THE INDIAN MEDICAL SERVICES.

Brigade-Surgeon-Lieutenant-Colonel S. M. Salaman has delivered over charge of the Yerrowda Central Prison. Surgeon-Captain J. Mulvany, on duty in connexion with famine relief, Mirzapore, is transferred to duty in connexion with precautions against bubonic plague at Manikpore in the Banda District. Surgeon-Lieutenant C. D. Dawes, on duty in connexion with precautions against bubonic plague at Manikpore in the Banda District, is transferred to duty in connexion with famine relief in the Hamirpore and Jalaun Districts. Surgeon-Captain H. B. Melville, Civil Surgeon, Second Class, sub *pro tem.*, to be confirmed in that appointment, but to continue to officiate as Superintendent, Central Prison, Lucknow. Surgeon-Captain J. Chaytor-White, Officiating Civil Surgeon, to be Civil Surgeon, Second Class, sub *pro tem.* Surgeon-Captain R. E. Molesworth, A.M.S., is appointed to the Civil Medical Charge of the Almora District, in addition to his military duties. Surgeon-Lieutenant-Colonel W. H. Cadge, Civil Surgeon, is transferred from the Medical Charge of the Camp of H.H. the Lieutenant-Governor and Chief Commissioner to the Bareilly District. Surgeon-Captain A. E. Roberts, Civil Surgeon, is transferred from Bareilly to the Medical Charge of the Camp of H.H. the Lieutenant-Governor and Chief Commissioner as a temporary measure. The Queen has approved of the following promotions among the officers of the Indian Medical Service:—Surgeon-Lieutenant-Colonels to be Brigade-Surgeon-Lieutenant-Colonels: Augustus Napoleon Rogers-Harrison, Madras Estabishment; William Reed Murphy, D.S.O., Bengal Establishment; and Charles Henry Joubert, Bengal Establishment. The Queen has also approved of the retirement from the Service of the under-mentioned officers:—*Bombay Establishment:* Surgeon-Colonel Robert Bowman and Brigade-Surgeon-Lieutenant-Colonel Selim Myer Salaman, M.D.

NAVAL MEDICAL SERVICE.

Inspector-General of Hospitals and Fleets Duncan Hilston, M.D., has been placed on the Retired List.

VOLUNTEER CORPS.

Artillery: 1st Edinburgh (City): Surgeon-Major J. J. K. Duncanson, M.D., to be Surgeon-Lieutenant-Colonel. *Royal Engineers:* 1st Lancashire: George Arthur Hawkins-Ambler, gent., to be Surgeon-Lieutenant. 1st Hampshire: Richard Emmett, gent., to be Surgeon-Lieutenant. *Rifle:* 5th (the Hay Tor) Volunteer Battalion the Devonshire Regiment: Surgeon-Lieutenant E. Haydon, M.B., to be Surgeon-Captain; Surgeon-Lieutenant J. Quick resigns his commission. 1st Volunteer Battalion the King's (Liverpool Regiment): Llewellyn Arthur Morgan, M.D., to be Surgeon-Lieutenant. 4th Volunteer Battalion the South Wales Borderers: John Howard-Jones, M.B., to be Surgeon-Lieutenant. 2nd Volunteer Battalion the East Lancashire Regiment: Surgeon-Lieutenant T. Holt, M.B., to be Surgeon-Captain. 1st Volunteer Battalion the Dorsetshire Regiment: Surgeon-Lieutenant H. F. T. Chambers resigns his commission.

VOLUNTEER MEDICAL STAFF CORPS.

The Manchester Companies: Surgeon-Captain I. J. E. Renshaw resigns his commission.

VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

A keen competition took place on Tuesday last, April 22nd, at the "Artists'" R.V. headquarters, Duke's-road, W.C., when a large number of non-commissioned officers and men of Volunteer Corps of the Home District competed for the Hamilton Challenge Bowl and other valuable prizes of the school. The winning team was composed of members of the Army Postal Corps—viz., Bugler Caney and Privates Perkins, W. Brecknall, and G. H. Haslewood, who obtained 423 marks out of a possible 480. The best man of the school was also found in the same corps, Colour-Sergeant Yardley coming out first with 114 points out of 120. The second team was composed of the newly formed bearer company of the Essex Volunteer Brigade, whose "turn-out" was extremely good; this team obtained 157 marks out of a possible 160 in drill. The subjects of the examination included elementary anatomy and physiology and first aid and stretcher drill. The examiners were Major Andrew Maclure (the President), Surgeon-Captains E. Hughes and G. Ferguson, Surgeon-Lieutenants C. Stonham and Berkley, Captain Lawther (statistical officer), and Surgeon-Captain R. R. Sleman (referee). The prizes will be presented at the inspection of the class on Tuesday, May 4th.

THE LATE MR. THEOPHILUS H. CLARKE.

It is fitting that one who was for so many years the chief clerk of the Army Medical Department of the War Office should not pass away without some tribute to his memory. Mr. T. H. Clarke died on Easter Day, 1897, at Beckenham, aged sixty-eight years. His duties brought him into intimate association with the heads of the Army Medical Department, and he was greatly respected and trusted by them all, and especially by the late Sir William Muir. Those who knew him best had entire belief in his integrity and simple-minded sincerity, for he was incapable of harbouring any mean or unworthy purpose; but, like so many men of this stamp in public spheres of occupation, he did not altogether escape, and could not hope to escape, calumny. It is, to borrow a phrase lately used, one of the perquisites of office, and, it may be added, usually a certificate also of a man's fitness for his post. Be this as it may, the late chief clerk was single-minded and untiring in promoting what he thought the true interests of the medical service and its officers, and we are assured he befriended many who never heard, and will never hear, of his work in this respect. He had many most sincere friends in the medical service to whom he was greatly attached, and, what, after all, is far better, a conscience void of offence.

THE HEALTH OF THE ARMY IN INDIA.

This still forms the subject of a good deal of discussion and correspondence, but without much advantage in the way of advancing our practical knowledge. There does not seem much to be gained by further reviewing the situation at the present moment. The Government of India, having received and considered Lord George Hamilton's despatch, have drafted some regulations in accordance therewith, and these have been submitted to a small committee composed of Colonel Badcock (quartermaster-general), Major Campbell (cantonment magistrate), and Surgeon-Major Williamson for consideration and report. The proposed regulations, when finally revised and approved by the Government of India, will be submitted to the India Office.

The annual mess of the Volunteer Medical Staff, organised by the Volunteer Medical Association, will take place at Limmer's Hotel on Wednesday next, May 5th, at 7.30 P.M. Sir William Mac Cormac, vice-president of the association and President of the Royal College of Surgeons, will take the chair. The Director-General A.M.D. (Surgeon-Major-General Jameson); Sir Francis Grenfell, G.C.M.G., K.C.B.; Surgeon-Colonel T. O'Farrell; and other distinguished guests have promised to attend.

The annual meeting of the Volunteer Medical Association will take place at 20, Hanover-square, on Wednesday next, May 5th, at 4.30. P.M.

Fourteen invalids for the Royal Victoria Hospital, Netley, left Egypt in the s.s. *Tabor* on April 15th.

On April 24th thirty-nine invalids were admitted to the Royal Victoria Hospital from Malta *ex* s.s. *Malacca*.

"Audi alteram partem."

"THE CONDITION OF THE PORTSMOUTH SLUMS."

To the Editors of THE LANCET.

SIRS,—An annotation under the above heading in THE LANCET of April 17th concludes with the following statement: "Assuming that these facts are correct the reflection on the sanitary authority is indeed a serious one." In fairness to Portsmouth and the sanitary authority may I ask you to insert the following.

I have visited every place mentioned in the local paper quoted from, and I find that the article is grossly exaggerated throughout. All the measurements given are inaccurate, and in every case they err in making out the places smaller than they really are. The language used to describe them is exaggerated and sensational in tone, and the whole article gives a totally erroneous conception of the condition of Portsmouth. So far from Portsmouth being a "slummy" place, there are few towns in the kingdom of its size and antiquity with fewer slums. The fact that Portsmouth for the years 1894 and 1895 had the lowest death-rate of any large town in the kingdom (with the exception of Croydon) speaks volumes for the health of the town and for the thorough and efficient manner in which the sanitary authority has for years past been carrying out its duties.

I am, Sirs, yours faithfully,

A. MEARNS FRASER.

Portsmouth, April 27th, 1897. Medical Officer of Health.

SENILE DECAY: ITS CAUSES AND TREATMENT.

To the Editors of THE LANCET.

SIRS,—May I add a few words to the report of the meeting of the Medical Society of London in THE LANCET of March 27th (p. 882)? At this meeting Dr. Savill read a paper of unusual importance, and I came up from Cambridge on purpose to hear it and to discuss it. This paper, I venture to think, should not have been put in the second place, especially when a surgical paper of considerable interest took precedence of it. As it was, the important subject introduced by Dr. Savill was very inadequately discussed by subsequent speakers, who rose by permission after the normal time of closure and spoke in haste and under constraint.

Dr. Savill gave the results of a minute pathological research based upon 400 necropsies and some thousands of microscopic sections in support of more than one conclusion. One of these conclusions is that a certain arterial degeneration is normal and inevitable in old persons. This conclusion I am said to have contested. For me to contest any of Dr. Savill's conclusions would be absurd; on the contrary, I recognised by my presence at the meeting the great value of his labours, and I said that I had no minute and exact pathological evidence of my own to set, however diffidently, against that of Dr. Savill. I did but venture incidentally, and on general grounds, to demur to immediate acceptance of this proposition in an absolute form. I have seen many very old persons in whom the arterial coats and the blood-pressures seemed normal to the clinical judgment, and a few in whom the heart and arteries after death, as observed only by the naked eye, seemed as those of young persons. Such cases are rare, I admit, but still, if one such case be proved in a person of, say, over fourscore, senile arterial degeneration can no longer be called "normal." Again, I suggested that Dr. Savill's necropsies being made upon workhouse patients—made, that is, upon persons with whom life had gone hardly—cannot, perhaps, be taken as complete evidence. But I now regret that I made even these small reserves, as, owing to the brevity of the proceedings, they came forward in disproportionate relief against the expressions of great satisfaction and admiration with which in all respects I ventured to greet Dr. Savill's essay.

This gratitude I personally felt the more as I was led to hope that Dr. Savill has proved on the pathological side certain observations which on the clinical side had occupied me for some twenty years. At the Hunterian Society and elsewhere I have described certain cases as "Senile Plethora" or "Arterial Hyperpiesis," but on their clinical aspect only, as after long delay I had never been able to secure a necropsy on such a patient. These cases, I believe, will turn out to be of the same kind as those described by Dr. Savill as "arterial hypermyotrophy." If this be so, I venture to hope that the description of a symptom-group of great practical importance, now fully recognised for the first time, will be placed on the firm basis which in my reports was lacking. I read with much interest that Mrs. Garrett Anderson has described similar cases from her own experience.

I am, Sirs, your obedient servant,

Cambridge. T. CLIFFORD ALLBUTT.

"RIGHT-HANDEDNESS."

To the Editors of THE LANCET.

SIRS,—Dr. G Archdall Reid seems thoroughly convinced that acquired characters are not transmissible. This is a much disputed point, as to which there is room for difference of opinion. Individually, I strongly incline to the views of Herbert Spencer rather than to those of Weismann on this subject In support of his opposite views Dr. Reid says: "Every man individually *acquires* the faculty of language and of bi-pedal progression in an erect posture; neither of these is instinctive or inborn, and therefore transmissible, and both result from the fact that the one generation acquires them by imitation from the preceding generation." This is a very dogmatic statement, against which much may be said. In your report of my first Lumleian Lecture[1] there is recorded a case of deferred and untaught speech which is adverse to this opinion. On mentioning this case many years ago to a distinguished physician (Sir Richard Quain) he informed me of a closely related fact. "His eldest daughter up to the age of two years had not walked a step, or even tried to walk, when one day he put her down in the standing position, and to his great surprise as well as to that of the nurse she walked from one side of the room to the other. This also was an untaught act, as there had been no previous trials and failures." The above sentences are quoted from my book, "The Brain as an Organ of Mind" (p. 607), and in the same work there is a section (pp. 561, 562) entitled, "Deferred Primary Automatic Movements," in which it is pointed out, in reference to lower animals, that "much difference exists among different animals as to the degree of perfection *at the time of birth* of these inherited cell-and-fibre connexions, and, therefore, similar differences exist among such animals in regard to their power at birth of executing the several movements with which such nervous mechanisms are in relation."

I am, Sirs, faithfully yours,

Manchester-square, April 25th, 1897. H. CHARLTON BASTIAN.

"PREMATURE BURIAL."

To the Editors of THE LANCET.

SIRS—Permit me to make a remark in relation to your observations in an editorial article in THE LANCET of April 24th on a passage attributed to me in inverted commas, describing the test of death by means of a vessel filled with water placed on the body of the supposed defunct. I have never seen the paper from which these words are taken. Some two or three months ago a literary acquaintance called on me to ask for any information I could give him on the subject in question. I learned from him that he was wishing to write something on the subject, and I was not aware that it was an "interview" or that my name was to appear. I remember that I mentioned, first, the well known value of the ligature with regard to blood circulation and other usual tests, and finally named, as of secondary value, that now under consideration. About a month ago I learned by accident that my name was appearing in some journal abroad in connexion with this subject, but I have never been able to ascertain whether any publication of my suggestions had taken place or not until my perusal of your article.

It may be appropriate to state here that in the form of

[1] THE LANCET, April 3rd, 1897, p. 933.

Hosted by Google

death certificate which I drew up some years ago for use by the Cremation Society the examination of the dead body and its personal identity is especially required from the medical man who certifies. I enclose you a copy, and will add that it met with the approval of the House of Commons Select Committee on Death Certification, and was by them recommended to take the place of the form at present employed. My approval of the French system as superior to our own is, I think, quite justified; the neglect of its requirements in practice, if it exists, is simply due to a defective administration of the law.

I am, Sirs, yours truly,

April 28th, 1897. HENRY THOMPSON.

"LUNACY IN EGYPT."

To the Editors of THE LANCET.

SIRS,—In an annotation on "Lunacy in Egypt" which appeared in THE LANCET of April 24th you state that "Dr. Warnock has been informed that some lunatics are kept in Damascus in stone cells, with chains round their necks." I can testify from personal observation that five years ago this form of treatment was actually in force in Damascus. In 1892 I visited the "lunatic asylum" in that ancient city and noted the following state of things. The institution consisted of a series of one-storeyed buildings surrounding a central yard, open to the air, which at that height (691 metres) is often very cold. There were seven cells opening on this yard, four double and three single. The single cells measured 8 ft. by 10 ft. They were built of stone, with stone floors, and the drainage system was simple, consisting as it did of a hole in the centre of the floor leading into a drain communicating to a cesspool (probably overflowing into the streams which run through the town and supply its drinking water). The floor was covered for half its extent by boards on which the patients lay. There was no furniture of any kind in the cells. In these seven cells were eleven patients—the term is very applicable—three or four of these were chained by the neck and legs to the wall. They appeared in great misery and imperfectly fed. No doubt they were dependent on charity for their support, and charity, even in a Moslem city, when it has filtered through the hands of Turkish guardians, is not very satisfying to its recipients. I need hardly add that these cells were very dark, being only lighted from the upper part of the doorway, which was built in the same way that stable doors are built here, and the smell was awful. These patients were probably all more or less violent, chronic maniacs, and such like, as the less troublesome lunatics in these countries are always kept by their relatives at home—and naturally. It was a dreadful and degrading sight, and made one shudder to think that man could become so like a wild beast.

So much for Turkey; but I was told a few years ago that in Greece an Englishman who had become acutely maniacal was treated in very similar fashion, being placed in a cell with an iron gate, through the bars of which his food was pushed, and the straw on which he lay raked in and out, and from this treatment he was with great difficulty rescued to be brought home to England. No doubt the state of things I witnessed at Damascus in 1892 has existed for centuries and will persist as long as the Turks hold Syria, but it can hardly be wondered at, under the circumstances, that, as Dr. Warnock says, "some Syrians are brought to Egypt on purpose to obtain 'admission' to the Cairo asylum."

I am, Sirs, yours faithfully,

April 24th, 1897. W. A. WILLS.

"THE QUESTION OF THE SECOND OVARY IN OVARIOTOMY."

To the Editors of THE LANCET.

SIRS,—The points raised by Mr. Clement Lucas in his letter in THE LANCET of April 24th are both interesting and important. I think most men will agree that the right treatment was adopted in removing a slightly cystic second ovary in a woman forty years of age. I go further, and say that in *all* cases of ovariotomy near or after the menopause the second ovary should invariably be removed, whether it looks healthy, cystic, or atrophied. With regard to the case of a woman, aged twenty-five years, whose second ovary contained a cyst the size of an orange, it seems to me that instead of leaving it alone it would have been better either to have removed it altogether or to have excised the cyst and left the ovary—a plan I have successfully adopted in several similar cases.

I am, Sirs, yours faithfully,

WILLIAM DUNCAN, M.D. Brux., F.R.C.S. Eng.

Harley-street, W., April 26th, 1897.

To the Editors of THE LANCET.

SIRS,—I read with interest the letter on the above subject from Mr. Clement Lucas which appeared in THE LANCET of April 24th. The opinion of a surgeon to a great medical school always deserves careful consideration. I cannot, however, say that I agree with Mr. Lucas's conclusions, as they do not accord with my own experience, dating from 1877, of a very large number of ovariotomies performed by myself and my colleagues at the Samaritan Free Hospital for Women and Children. Mr. Lucas holds that little *surgical* training is requisite for ovariotomy. It would have been more correct to say that not very much *anatomical* training is requisite; yet such a statement might do harm. The relations of the tumour to the pelvic viscera, the ureters, and the great vessels must be well understood by the beginner. Few operations test a man's surgical capacity better than that in question. I have known of terrible results due to an operator committing the grave error of making too light of an easy case or mistaking an innocent semi-solid ovarian tumour for a malignant growth, closing the wound and letting the patient die from hæmorrhage. Mr. Lucas is, on the other hand, much to be commended for looking on double ovariotomy as serious even when imperatively needed. My own views on the question will be found in a contribution to THE LANCET[1] entitled "Two Cases of Ovariotomy Performed Twice on the Same Patient." In 1889 I removed a papilloma of the right ovary from a woman aged fifty years. The left ovary, as I noted at the time, was elongated and atrophied. I considered that its removal was not justifiable, and I remain of the same opinion. The disease recurred in 1894 in the remaining ovary, which I took away without trouble. I wrote in the above paper: "Had I removed the flat, atrophied, apparently healthy ovary in 1889 I should have spared both myself and the patient much anxiety and two troublesome complications, which both recurred at and after the second operation. Yet surgeons are not prophets, and the chance of so atrophied an ovary becoming diseased seemed slight in 1889. The surgeon should hesitate to remove a sound organ on the strength of a theory." By "theory" I meant that of Pfannenstiel quoted in my contribution. Sir Spencer Wells declared at a meeting of an American society in 1888 that "if there is no suspicion of disease I do not remove it (the second ovary)." Howard Kelly's statistics support this principle.

When the second ovary is clearly diseased the case is quite different. The further development of a cystic tumour is all but certain, and is an intolerable annoyance to the patient. Cystic disease is not very difficult to diagnose when the ovary has grown to the size of a walnut. "A cyst as large as an orange" is pathologically, clinically, and surgically a tumour, and should be removed. I regret that Mr. Lucas should write down his opinion that when both ovaries are removed "a woman from that time forth is an unnatural monster cut off from the next generation." I know of a considerable number of patients where I and my colleagues have thought it right, on the above principles, to remove the second ovary, and not one of them is in any sense an "unnatural monster." Such a term might as well be applied to any spinster or any married woman sterile from uterine disease. The troubles of a premature menopause are far more tolerable than the worry and danger of recurrence of cystic disease in the remaining ovary. As for certain severe neuroses, they are known after the simplest unilateral ovariotomy.—I am, Sirs, yours faithfully,

ALBAN DORAN, F.R.C.S.Eng.,
Surgeon to the Samaritan Free Hospital for Women and Children.

Granville-place, Portman-square, W., April 26th, 1897.

To the Editors of THE LANCET.

SIRS,—The extraordinary sentences which open Mr. Clement Lucas's letter made me look carefully at the top of

[1] THE LANCET, Dec. 15th, 1894, p. 1415.

Hosted by Google

the page to see that dates were right, to make sure I was not reading a copy of your ancestor's journal of 1837. Is it possible that such a view can be held about any operation in surgery, much less concerning one about which there is always so much doubt till it is over? Yet there the words stand. A woman with both ovaries removed for cystic disease does not become an "unnatural monster"; nor is she cut off from the next or any other generation; nor does she stand in the least danger from this cause of being divorced.

Mr. Lucas is a lecturer on anatomy and surgeon to Guy's Hospital and an examiner in anatomy at the Royal College of Surgeons of England, and he records this in your columns this morning: "She was only twenty-five years of age and was found to have a large unilocular cyst of her right ovary, which contained ten pints of fluid, and connected with the left ovary was a cyst as large as an orange. The right ovary was easily removed and the other was left." The tumour which he removed was not a tumour of the ovary at all, but a tumour in the broad ligament, from which the ovary could easily have been separated by a skilled anatomist and left. The second tumour was probably the same, and if so, simple enucleation would have spared the patient the risk of a second operation and both ovaries. There is really no need to remove healthy ovaries at all; besides, it is getting dangerous and had better be carefully avoided. Deliberately to leave cysts is, however, very bad practice, according to my experience and belief.

I am, Sirs, yours truly,

Birmingham, April 24th, 1897. LAWSON TAIT.

To the Editors of THE LANCET.

SIRS,—It is difficult for some of those who are interested in abdominal surgery to accept with complaisant acquiescence Mr. Clement Lucas's views contained in his letter in THE LANCET of April 24th on the treatment of the second ovary in ovariotomy. The advice he gives there as I read it is, "where one ovary is extensively diseased and the other only in the early stage of cystic degeneration," unless the patient is past the child-bearing epoch, that only "the extensively diseased ovary" should be removed, for by removing both "the woman from that time forth is an unnatural monster, cut off from the next generation, and if married with the condition secreted" presumably "liable to be divorced"; and also "should the cystic degeneration increase rapidly there would be no great danger in operating a second time for the removal of the second ovary." I have always been under the impression that it was the duty of the surgeon invariably to ascertain the condition of the second ovary at the time of operation and unhesitatingly to remove it if it were found to be indubitably the seat of disease, although only in an early stage. I believed this to be an accepted surgical rule admitting of little latitude of choice.

If the second diseased ovary is removed, together with the more extensively diseased one, the operation is not thereby made of greater gravity to any appreciable extent. Why, then, should so favourable an opportunity be neglected of radically dealing with the whole disease before the complications, if hitherto absent, to which such tumours are liable, have a chance of developing, as they may do between the two operations if each ovary is dealt with at a separate time? For it is surely quite the exception to observe an ovary, definitely affected with cystic degeneration, enlarged, for example, "to the size of an orange," as in Mr. Lucas's case, remaining in a resting state; the large majority increase steadily, although their rate of growth may vary widely. Moreover, should any patient be subjected, except for most adequate reasons, to the discomforts and risks of a second operation—an operation which, however Mr. Lucas may minimise it as a surgical procedure, still remains a laparotomy, one that certainly few would care to submit to oftener than necessary? Then is every woman who has had the ovaries removed of necessity "from that time forth an unnatural monster, cut off from the next generation"? I for one should be sorry to believe it. Moreover, her connexion with the next generation may have already been secured if she has borne children. That menstruation often continues after double oöphorectomy is a well-established fact. From my own observations I am convinced that the female temperament is much less influenced by this operation than is generally supposed to be the case; certainly to an infinitely less extent than the male temperament by the corresponding operation. Even when the second ovary left, because normal to all appearance, it often in turn undergoes cystic degeneration and the patient has a second time to undergo ovariotomy, and occasionally troublesome complications arise when pregnancy closely ensues upon ovariotomy, as in a recent case under my care where I operated upon a partially irreducible ventral wound-hernia, causing great inconvenience, which had occurred during the pregnancy and was greatly aggravated by the enlarged uterus.

The medico-legal aspect of Mr. Lucas's supposed case, where a woman marries having concealed from her husband the fact that a double ovariotomy had been previously performed upon her, is only of collateral interest and relatively unimportant. But I cannot see that the subterfuge is much less to conceal the fact that one ovary has been removed and the remaining one is known to be cystic "to the size of an orange," as in Mr. Lucas's second case, than to suppress the fact that both ovaries have been removed. Possibly the suitor of such a patient, if possessed of some medical knowledge, might think the latter the lesser ill.

I am, Sirs, yours truly,

J. H. DAUBER, M.B., B.Ch.Oxon., M.R.C.P.Lond.,
Assistant Physician, Hospital for Women, Soho.

Charles-street, Berkeley-square, W., April 27th, 1897.

EPILEPSY AND MARRIAGE: A SUGGESTION.

To the Editors of THE LANCET.

SIRS,—I venture to think that it will be a pity if the interesting correspondence upon the marriage of epileptics should close without some practical good. As a contribution to the theoretical and scientific side of the question the letters you have published have a value of their own; but, apart from this, we are not much nearer the actual facts as to the influence of marriage and epilepsy upon each other. There must be few of your readers who have not had opportunities of becoming acquainted with the history of one or more married epileptics and the effect, if any, on the offspring; and if we could induce you to receive, and your readers to send you, the family histories of cases which have come under their observation a store of facts would be accumulated of more use and practical value even than the instructive correspondence which has just closed.

I am, Sirs, yours faithfully,

April 26th, 1897. NORMAN PORRITT.

"THE MIDWIVES REGISTRATION BILL."

To the Editors of THE LANCET.

SIRS,—There having been some delay in the publication of my letter, which appeared in THE LANCET of April 24th, I wish to say that on April 14th Mr. Skewes-Cox, Member of Parliament for the Kingston Division (Surrey), requested me to supply him with a copy of my "Sick and Obstetric Nurses Bill," as outlined in my letter, and I therefore drafted a bill of nine clauses with schedules and sent it on April 19th to the hon. member, who is giving it his careful consideration. It is an adoptive measure, and would be administered by boards of guardians, county, district, and parish councils, or by voluntary nursing associations. Clause 3 renders it "unlawful for any person (male or female) to assume the title or to practise as a midwife, sick or obstetric nurse, without the supervision and control of a fully qualified and registered medical practitioner." Clause 4 provides for "a certificate of competency from a duly recognised teaching authority for every woman acting as sick, monthly, or obstetric nurse." Clause 5 makes it compulsory for boards of guardians to "adopt" the Act in default of other local authority. Clause 7 prohibits both sick and obstetric nurses "from prescribing or administering any noxious drug or using any surgical instrument (apart from those necessary to their calling) or signing any death certificate or certificate of still-birth or of illness for any club or benefit society, the penalty for any one of these offences being three months' imprisonment and dismissal by the authority under which she is acting." This clause would extinguish the female prescriber and abortion-monger once for all. Clause 9 deals with boards of guardians and the fees payable to medical men. These are all on the basis of the Consolidated Orders, but mileage is to be paid for above a mile from the medical man's residence. The schedules deal

Hosted by Google

with the administration of the Act, the training of the sick and obstetric nurses, their pay, &c., and I have suggested three grades of sick nurses, with six, eighteen, and thirty-six months' training respectively, their pay being £60, £80, and £100 respectively. Obstetric nurses with a minimum of three months' training to have £60 per annum, both classes being prohibited from accepting fees and gratuities from patients and their friends. The schedules also contain rules and regulations for both the nurses and the medical men. The bill is intended as a compromise, and is drafted on the principle that its working would be largely carried out by voluntarily nursing associations, with "grants in aid" from boards of guardians and local authorities.

I am, Sirs, yours faithfully,

April 27th, 1897. ALEX. MCCOOK WEIR.

"NEW SANITARY BY-LAWS FOR LONDON."

To the Editors of THE LANCET.

SIRS,—In your commentaries upon the proposed new sanitary by-laws of the London County Council in THE LANCET of April 24th you criticise By-law 7, in reference to gulleys being placed outside buildings and waste-pipes discharging over them, saying on page 1165, "With new buildings there can be no difficulty," and again, "New buildings must not be allowed to offer any difficulties." If reference be made to the London Building Act, 1894, it will be found that new buildings erected in existing streets—and this applies to the whole of existing London—may be made to cover the whole of the ground area of the premises, and my experience is that this is taking place. I have a number of examples in which this has taken place during the two years the Act has been in force. If, therefore, under the Building Act, it is possible to cover in all the ground space, and owners avail themselves of the opportunity, how is it possible for the new sanitary by-laws to be enforced?

I am, Sirs, yours faithfully,

JOHN F. J. SYKES,
Medical Officer of Health of St. Pancras.

Camden-square, N.W., April 26th, 1897.

"NOTES ON ONE YEAR'S SURGICAL WORK."

To the Editors of THE LANCET.

SIRS,—Mr. Symonds, in THE LANCET of April 17th, reports that of four cases of flat-foot two were treated by excision of the metatarso-phalangeal joint, and that "by this means the inner aspect of the foot was shortened and a permanent arch was formed." I am wholly unable to see how such an operation can have this result. I could understand if it led to the *effacement* of an existing plantar arch, because it involves destruction of a joint necessary for proper action of the flexor longus pollicis muscle, which "is the real sustentaculum tali." I am here adopting the words of Mr. Barwell in THE LANCET of Jan. 30th, where, in another very happy expression, he speaks of the arch as "a by-product of function"; and I note them with satisfaction as expressing principles on which I have for many years been insisting in these columns, in "The Human Foot," and elsewhere. To those principles the operation recorded, and presumably recommended, by Mr. Symonds is altogether opposed.

I am, Sirs, yours faithfully,

Gloucester, April 23rd, 1897. T. S. ELLIS.

THE ALLEGED INCREASE OF INSANITY.

To the Editors of THE LANCET.

SIRS,—I have carefully studied the special report of the Lunacy Commissioners recently laid before Parliament and admit that insanity, as such, especially in lunatic asylums, may possibly not have increased so much as the number of registered lunatics. I also thoroughly appreciate the thirteen reasons put forward by the Lunacy Commissioners to account for the increase in the number of insane persons; but still it cannot be denied that in thirty-seven years the number of lunatics has increased from 37,762 to 96,446, and will probably continue to increase. Even if these numbers do not constitute "a serious menace to the race," there still, according to my views, remains to the State, and especially to so rich a State as England, the right and duty to seek out and adopt measures for the purpose of limiting as much as possible this increase of insanity, more especially as pauper lunatics will probably, as time goes on, make still further claims to assistance. The thirteen reasons brought forward by the Lunacy Commissioners to explain away the continual increase in the number of lunatics do not take into account heredity and abuse of alcohol. These chief causes for the breaking out and further increase of mental disorders remain unchallenged, and as long as they are not combated by the State the number of lunatics, together with mental disorders, will continue to increase. Most scientific specialists in England will be disposed to concur in these views.

I am, Sirs, yours faithfully,

DR. F. SCHLANGENHAUSEN.

Villach, Carinthia, April 20th, 1897.

HOSPITAL ABUSE.

(BY OUR SPECIAL COMMISSIONER.)

VIII.—THE ROYAL LONDON OPHTHALMIC HOSPITAL.[1]

The Crowd of Patients and Students from all Parts of the World.—The Guinea Fee Limit.—The Difficulty of Dealing with Poor Patients willing to Pay.—A Partial Check on Abuses.

IT is a general complaint in the provinces, but more especially in the smaller towns, that the London hospitals compete disastrously, not only with the local general practitioners, but even with the consultants. Where there is a serious illness or the necessity for an important surgical operation, the patient often has not sufficient faith in the ability of the general practitioner and shrinks from the expense of applying to a consultant. Perhaps also his faith in the provincial consultant is hardly any firmer than his faith in the provincial general practitioner. Hence the tendency, which easy railway communications have greatly increased, to go to London for superior advice. At Leeds, for instance, I was told of a case of a boy who suffered from tuberculosis of the foot. His parents had heard that Sir James Paget was attached to the staff of St. Bartholomew's Hospital, so without further inquiry the boy came up to London. He was under the impression that he would at once be seen and cured by this eminent surgeon. On reaching London he presented himself at St. Bartholomew's Hospital and forthwith asked to see Sir James Paget. The attendants expostulated in vain. The boy took a seat and patiently remained there for four hours. He returned the next day and for several days, and it took some time before it was discovered that the money spent in the journey to London would have sufficed to pay for expert advice in Leeds.

Of the various diseases for advice for which patients can easily come up to London diseases of the eye hold a prominent place. Generally there is no immediate urgency, so that the patient can select his own time for the journey, and as his general health is not impaired he can travel without risk or inconvenience. The temptation in those cases to go to London is all the greater, as the Royal London Ophthalmic Hospital enjoys a world-wide reputation. This was the first institution of the kind founded, not merely in England, but in Europe. It was established in 1804, and then called the "London Dispensary for the Relief of the Poor Afflicted with Eye Disease." The following year the hospital was opened, and during the first twelve months over 700 patients were treated. In 1821 the foundation-stone of the present building in Moorfields was laid. The number of patients, however, increased so rapidly that a new wing had to be added in 1869, and now a special appeal is made for the purpose of erecting a still larger and more suitable building in the City-road. In 1895 there were 28,474 patients treated at this hospital, an increase of 1982 on the previous year. Of this number 2184 were in-patients, of whom 825 were operated on

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Sept. 26th, 1896, Plymouth and Devonport; (2) Oct. 10th, 1896, Exeter; (2 *continued*) Oct. 17th, 1896, Exeter; (3) Oct. 31st, 1896, St. Thomas's Hospital, London; (4) Nov. 14th, 1896, Liverpool; (4 *continued*) Nov. 21st, 1896, Liverpool; (4 *continued*) Dec. 12th, 1896, Liverpool; (5) Jan. 2nd, 1897, Manchester; (5 *continued*) Jan. 9th, 1897, Manchester; (5 *concluded*) Jan. 23rd, 1897, Manchester; (6) Feb. 6th, 1897, Leeds; (6 *concluded*) Feb. 13th, 1897, Leeds; and (7) April 17th, 1897, Coventry.

Hosted by Google

for cataract. The total attendance of out-patients amounted to 131 450 visits, giving an average of more than 400 patients for each working day. Nevertheless this does not suffice, and no inconsiderable number of patients have to be turned away unrelieved. The fact is that the Royal London Ophthalmic Hospital is known to be one of the best schools in the world for ophthalmic surgery. The most eminent ophthalmic surgeons have been members of the staff or students at the hospital, and this reputation is not merely national, but international. Many Germans and Frenchmen come to study at this hospital, as do hundreds of Americans. One of the latter recently said: "We in America think no ophthalmic surgeon can hope for salvation unless he has visited Mecca once." Of course, the Royal London Ophthalmic Hospital is the Mecca in question. Now medical men can scarcely complain if the opinions they entertain are also shared by their patients. The latter hope to obtain the advice of the most eminent visiting surgeons, and know that the assistants and house surgeons are also all highly qualified, some having served on the staff for six or seven years. Patients come from all parts of England and also from abroad and from the colonies. Many patients come from Australia, New Zealand, and the Cape. They hoard up all they can so as to pay for the journey, in the hope of preserving their sight. A large number of medical men have been trained here so as to set up independent centres elsewhere; but this generally fails to divert the current that flows towards the parent institution. A short time ago an artisan arrived from Peru. Possessing hardly any money, he had to work his passage over. It is, however, noted that there are fewer patients from towns where there exists an ophthalmic surgeon of undoubted ability. Some such English provincial towns were mentioned to me; while from other towns, likewise mentioned, where the local ophthalmic surgeons do not enjoy such high repute, a great number of patients come to the Royal London Ophthalmic Hospital. From this it is inferred that the lack of skill on the part of local specialists is one of the causes of hospital abuse. For instance, not long ago a lady consulted the most eminent local ophthalmic surgeon of the provincial town where she resided. He told her that she must have glasses; that if she did not have glasses she would have strabismus and many other evil consequences would ensue. The lady consulted this surgeon several times. He applied atropine four times and in all devoted five hours to the examination of her eyes, but finally had to confess that he could not find any glasses that would suit her. In despair the patient came up to London. The case was difficult, but nevertheless in an hour and a half at Moorfields all the difficulties were overcome, and the suitable glasses provided. Patients cannot be blamed for going where they obtain the best results; and if these patients are not on the ground of poverty entitled to receive such advice, many will not hesitate to pretend that they are poor.

It must be confessed that the methods adopted to prevent such abuse do not seem likely to be very effective. Till within the last three years no system whatsoever was enforced. If there was anything particularly suspicious in the appearance of a patient, he was referred to the secretary. Though there were on an average some ninety new patients per day, only three or four were thus sent up to the secretary. But this was not of much use; they were judged, not from inquiry, but from their dress, and generally seemed to be poor people who had to keep up appearances. Indeed, the dress test, especially when applied to women, is of very little value. A tidy, orderly woman, with good taste and very little money, will appear far more stylish and better dressed than a slatternly woman who has ample financial resources. Besides, mere questioning is scarcely a sufficient test. Thus, several years ago a man was sent up to the secretary for inquiry; he looked respectable and appeared as if he possessed money. In answer to questions he declared that he had lost all his money in South Africa in consequence of the defeat of the British troops at Majuba Hill, and held forth eloquently against Mr. Gladstone's Transvaal policy. The secretary was not altogether convinced; he put it as a matter of honour to the applicant not to take up the place of the poor if he had the means to pay, and then consented to admit him on the patient's own moral responsibility. This patient remained at the hospital a little time as an in-patient and then fell ill from some other disease, and therefore had to be removed to the London Hospital, where he died. It would seem, however, that as he felt his end approaching he was struck with remorse, for he made a will on his deathbed and left the Royal London Ophthalmic Hospital a legacy of £500.

Three years ago, with a view to preventing abuse, the services of a former officer of the Charity Organisation Society were permanently engaged to act as inspector when new patients presented themselves. There is no wage limit. The inspector must try to ascertain whether the applicant can afford to pay a guinea, and, if so, he must send him away. In the course of the year 1895 he thus sent away no less than 823 patients, most of whom admitted that they could pay a guinea. During the previous year 412 applicants were refused admission. They were, for the greater part, people who went for glasses. One among them was a lady who said her husband was a clerk, but the inspector ascertained that the clerk received £300 a year. A good many clerks and persons in similar occupations go to the hospital. If they are in receipt of but a small salary they will very readily give the name and address of their employers. If, on the other hand, they are in receipt of a good income they are ashamed to mention their employer's name for fear that inquiries should be made. Under those circumstances they generally complain about the inquisitorial character of the proceedings and go away in disgust. Patients who go with a practitioner's card are examined like all other patients, unless they are specially recommended to one particular surgeon; in that event the matter is left to the discretion of the surgeon in question. Then there are patients who have been to the hospital some hundred times. These could afford to pay a few guineas, but certainly could not pay a hundred guineas. Patients from the provinces who possess some means generally come up to London to privately consult an ophthalmic surgeon, and after having paid a few guineas for such consultations find they cannot afford the cost of an operation. Under these circumstances they are admitted at the Royal London Ophthalmic Hospital. Others, who could pay a general practitioner, come for the special advice they could not obtain for less than a guinea. It must be borne in mind that no class of patient gives so much trouble, and that the guinea and even the two guineas fee is very often but a small remuneration in comparison with the trouble, occasioned. A difficult case may take two hours to investigate. Half an hour is given at a time to each eye and this is done in stages. A very simple case for spectacles will take twenty minutes, and the general practitioner, even if he is competent, cannot afford to give twenty minutes for a half-crown fee, particularly as the case may require not twenty minutes but a couple of hours. Many patients think that they only want a pair of spectacles, and are quite surprised to find that there are serious difficulties and complications. Numerous patients suffer from persistent headaches due to errors of refraction. It is then necessary to estimate the optical errors, and the case can scarcely be dealt with in less than three quarters of an hour. It is not reasonable to say that because patients can pay 2*s.* 6*d.* they should be referred in such cases to a general practitioner.

The great difficulty is to know what to do with the patient who can afford, and is willing to pay, some ten guineas for an operation. Many people write to members of the hospital staff saying that they have neither the time nor the health to wait for hours in the crowded out-patients' ward and are anxious to be allowed to pay a small fee so as to avoid this hardship. But the leading ophthalmic consultants have to send away daily patients who pay the highest fees, simply because there is not time to see them all. Why should they still further neglect their rich patients so as to see at reduced fees poorer patients? Their natural tendency is to refer these poorer patients to the hospital, where, by the subdivision of labour, the work is more rapidly accomplished. This argument more particularly applies to the operation for cataract. A patient will come, pay his guinea, and will ask what is the fee for the operation. Perhaps he is told 100 guineas. Then he pleads and describes his poverty, and asks what is the very lowest sum charged to poor persons, and probably he is told 50 guineas. Thus a poor man once applied to one of the operating surgeons of the Royal London Ophthalmic Hospital, and explained that he did not like the idea of coming to the hospital. He had during a long life of toil saved £120 for his old age. Out of this he would willingly pay ten guineas if he could have the cataract removed at his own home. This,

Hosted by Google

he thought, was a very great sum to offer. It is impossible not to sympathise with such a man. He did not wish for charity, and yet no competent surgeon could undertake such an operation for such a fee unless purely as an act of charity. Then such patients appeal pathetically, and insist that there must be at least some younger surgeons who would perform the operation for about ten guineas. But no operator who is really worthy of the name could do this for so small a sum. Even for normal cases of cataract the patient must be visited twice a day for from five to seven days, then once a day for two weeks, and three or four visits should be paid during the fourth week. After that one or two more visits are required for working out the glasses. Thus the patient has to be seen some twenty times at the cost of from fifteen to twenty hours, so that the ten-guinea fee would barely exceed half a guinea per hour. But complications may arise. For instance, a case was mentioned to me of a woman who had almost recovered from an operation for cataract when she caught cold. This occasioned complications, so that the attendance had to be continued for two months, involving in all seventy-eight visits, and yet the operating surgeon had no claim for an extra fee. It will be seen, therefore, that fifty guineas is not an extravagant sum to charge, and yet the vast majority of likely patients cannot afford to pay this amount.

At the hospital, however, the position is quite different. Here the busy ophthalmic surgeon would undertake operations for five guineas which he would not accept in his private practice for fifty guineas. If the typical ten-guinea patient were allowed to give five guineas to the surgeon and five guineas to the hospital, a very pressing demand, I was assured, would be met. All the subsequent visits after the operation for cataract, which take up so much time, would be avoided at the hospital, as this is done by the house surgeon. The operator does not see the patient again for perhaps a week, and has little or no further trouble unless complications arise. The advantage of subdivision of labour in such cases is obvious; but would not abuses arise in this as they have arisen in the ordinary paying wards of the various hospitals? The public is apt to consider that where payment is accepted that payment is sufficient, and it would be difficult to persuade a person who has given ten guineas that he is the recipient of a charity. Those who could afford larger sums would naturally think it was of no use to give more. Still, it does seem absurd to refuse sums that are often offered and would willingly be given because these sums are not large enough to make it unnecessary for the patient to go to the hospital. It is because ophthalmic surgery is so expensive that many comparatively well-to-do people go to the hospital. Many out-patients go to the Royal London Ophthalmic Hospital for advice which is subsequently carried out by their private practitioner. This class also might be made to pay a small fee; but because they cannot pay a guinea they must pay nothing at all.

About twenty years ago the visiting surgeons used to receive some of their private patients in the dining-room of the hospital. These being for the most part City men found it more convenient to go to the hospital than to go to the West-end consulting-rooms. This accounts, perhaps, for the impression, which still survives in the provinces, that rich people can go to the hospital, and this may be the origin of some cases of abuse. On the other hand, it was pointed out to me at this hospital that the cases of abuse were sometimes very much exaggerated. Thus, a medical man in the North of Scotland recently complained that the wife of one of his patients had been operated on for cataract at the Royal London Ophthalmic Hospital. He said that this patient was a market gardener and a ship-owner. The hospital authorities consequently made inquiries, and they ultimately ascertained that the patient in question cultivated vegetables on half an acre of ground, and owned the sixtieth part of a fishing smack, but his best source of income and his real trade was that of a cobbler. Another case was shown me of a woman who was very well dressed and seemed to hold a good position, but on being hard pressed with questions she had to confess that her husband was a bankrupt.

Such, as far as I was able to ascertain by inquiries made at the hospital, is the present state of affairs at the Royal London Ophthalmic Hospital. Considering that the patients are not visited in their own homes, and that the only form of investigation to which they are subjected is the cross-questioning which they have to undergo at the hands of the inspector especially appointed for that purpose, it is obvious that cases of abuse could easily escape detection. Nevertheless, it is a satisfaction to know that every year some hundred applicants are turned away because it is found that they can afford to pay guinea fees.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Hydrophobia and the Muzzling Order.

TWO cases of hydrophobia have lately occurred in this town, in consequence of which a muzzling order for dogs in the midland district has been issued. Much annoyance is felt by the owners of dogs, but the value of the order cannot be questioned when the comparison of the risk to human life is considered. In another instance the occurrence of hydrophobia in a patient after being bitten by a cat has excited an amount of apprehension. Expert authorities do not deny the existence of rabies in cats, but as these animals generally do battle with their claws rather than with their teeth the evil consequences of inoculation do not so often happen. Some protection is necessary when cases of undoubted rabies occur, and the desirability of stamping out the disease must commend itself as an act of justice to the community.

Cycling Fatality.

The death of a professional cycle rider formed the subject of an inquest at the Victoria Courts on April 23rd. Mr. A. W. A. Harris, a well-known rider, when engaged in a race at the Aston grounds, fell heavily from his machine, the front wheel of which had collided with the hind wheel of a rider's cycle in front. The pace at which Harris was riding was stated at the inquest to be twenty-four or twenty-five miles an hour. The death, which happened in the hospital, was found to be due to fracture of the base of the skull. Some criticism has been expressed as to the danger of an asphalt track for cyclists, but it was shown that this was rough and not smooth, not even so smooth as a cinder track.

Hospital Reform.

A meeting was held on April 21st at the Grand Hotel under the auspices of the Hospital Reform Association, having been called by circular expressing the aims and objects of the association. A variety of opinions were expressed as to principles and details. The resolution carried was "that this meeting of the medical profession practising in Birmingham and the district are of opinion that the question of hospital reform should be dealt with without further delay by the lay managers and acting staffs of our various hospitals and dispensaries, and thinks the recommendations issued by the Hospital Reform Association for the better regulation of the out-patient and casualty departments are worthy of their close consideration." It was stated that Birmingham wanted the reform very badly indeed. Last year the number of people relieved in Birmingham, including in-patients and the patients of the West Bromwich Hospital and the General Dispensary amounted to something like 228,738. The general practitioners were advised to take the matter up for themselves if the authorities did not do something towards it. The subject is undoubtedly a great one to deal with; existing barriers of tradition and custom have to be broken down before the ground can be cleared for a change. The tendency of opinion is certainly in the direction of reform, towards which it is expedient that the public should be educated in their own as well as in professional interests.

April 27th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Hospital for Incurables.

THE twentieth annual report of the Mauldeth Hospital states that in November last the number of in-patients, including those at Walmersley, was 110, of whom 29 were males and 81 females, 37 of the latter being at the Walmersley Branch, near Bury, which is designated in full as the Robinson Kay Branch of the Northern Counties Hospital for Incurables. This branch home, to which female patients only are admitted, was a gift from Miss Kay as a memorial of

Hosted by Google

her parents and was opened seven years ago. The house is placed in extensive grounds on the uplands adjoining Summerseat, near Bury. Last year the income of the two homes, including a donation of £320 from the Hospital Saturday and Sunday Funds, was £5151, against an expenditure of £5553. Mauldeth Hall is a large country house, about five miles from Manchester, and was at one time the residence of the Bishop of Manchester, but it was given up for the more conveniently situated Bishopscourt.

Child Labour.

In his address at the Conference of the National Union of Teachers, held at Swansea on April 20th, Mr. Adliscot, the president, made some remarks on the subject of child labour that ought to be thoughtfully pondered by the people of Lancashire. "The operatives of one town alone, Oldham (our close neighbour), put away £200,000 for the annual week's holiday, while they sent their little eleven-year-old offspring into the mills to help earn it." ..... "In England we kill them by inches, and we do it in the interest of trade and in the fear of German competition, oblivious of the fact that—and here I quote the recent report of Sir Philip Magnus—'child labour has practically disappeared in German factories.'" He went on to speak of the evils produced by "this miserable half-time system" by which half the day is supposed to be given to education and half to toil. Health and morals both suffer. "Take the blackest among our own counties. Lancashire shows the lowest ratio of pauperism, and, in spite of this, the highest ratio of juvenile crime; but Lancashire is the home of the half-time system." One undesirable result of the women working at the mills from childhood is that they grow up and marry—as a rule, very young—without any knowledge of the art of cooking. Frequently enough little or no cooking is done at home, partly from want of time and partly from ignorance or dislike of trouble, and the cook shops supply the food.

Manchester Royal Infirmary.

At a meeting of the board of management of the Manchester Infirmary, held on April 26th, Mr. J. Whitehead said he had been requested by the sons of the late Mr. Thomas Roberts, who was for many years a member of the board, to state that they wished to endow a bed in the infirmary in memory of their father. The only condition attached to the gift was the significant one that the bed should be in an infirmary on the present site in Piccadilly. The chairman said the announcement was most welcome, and asked Mr. Whitehead "to convey to the sons of their old and valued friend Mr. Roberts an expression of the grateful thanks of the board for their generous proposal."

Clayton Old Hall.

Through the generosity of Lord Egerton of Tatton a most interesting and ancient mansion—Ordsall Hall—is being preserved for Salford, and will be used as a museum. The corporation have acquired the house and grounds of Clayton Old Hall, and it is said that the land is to be laid out as a recreation ground and public park. It was one of the residences of Humphrey Chetham, whose name, even to many outside Manchester, is well known in connexion with the Chetham College and Library.

April 27th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University.

THE statutory half-yearly meeting of the general council was held last week, Principal Sir William Muir presiding. The draft ordinance issued by the Universities Commission instituting a "Professorship of Public Health and Sanitary Science (to be called the Bruce and John Usher chair of Public Health)" was approved. The professor of this new chair is to have a salary of not less than £600. Mr. A. L. Bruce's bequest was "in acknowledgement of Pasteur's investigations." The number of medical students shows a marked falling off; the numbers are as follows: 1891-2, 1951; 1892-3, 1736; 1893-4, 1560; 1894-5, 1512; and 1895-6, 1455.

Edinburgh Royal Infirmary.

At the half-yearly meeting of the Royal Infirmary managers held this week it was mentioned that the more general use of antitoxins in the treatment of diseases was adding largely to the medical expenditure, one case of tetanus, which happily recovered, having required between £50 and £60 worth of the remedy.

Opening of the Summer Session.

The summer session of the medical classes in Edinburgh will open on Tuesday, May 4th.

Glasgow Medico-Chirurgical Society.

This society met on April 23rd. The chair was taken by Professor McCall Anderson. Dr. J. H. Teacher gave a microscopical demonstration illustrating the Varieties and Life-Histories of the Parasites of Malaria and Malarial Fevers. In addition to describing the forms and development of the parasite Dr. Teacher gave an account of his experience of malarial fever as met with in the southern districts of Spain, and remarked on the great practical importance of the examination of the blood in the differential diagnosis between the irregular forms of malarial fever and other febrile conditions with which such forms have much in common. Dr. Middleton gave an account of two cases of Beri-beri. The patients were young men (Lascars), and displayed the usual symptoms of the disease, including muscular weakness, absence of the knee-jerks, and œdema of the lower limbs; there was, however, no pronounced muscular wasting, no reaction of degeneration, and no cardiac hypertrophy, and the urine in each case contained albumin. Six other members of the crew—the men were sailors—had been similarly affected. Dr. W. K. Hunter gave an account of the Bacteriological Examination of the Blood. The microbe described by Pekelharing and Winkler was discovered in the blood of each patient, and cultures and microscopical specimens of the organism were shown to the society. In addition Dr. Hunter related the Results following the Inoculation of Rabbits with the Micro-organism, and showed specimens demonstrating the occurrence of Peripheral Neuritis in the animals subjected to this experiment. Dr. Barclay Ness gave an account of a case of Myxœdema occurring in a man the subject of organic heart disease. Repeated attempts to practise the thyroid treatment had to be discontinued in consequence of the development of febrile disturbance and of cardiac respiratory distress. The case proved fatal, and specimens demonstrating the histological changes in the thyroid gland, skin and other organs were shown to the society. In the thyroid gland, which only weighed 83 grains, there was an extensive new formation of fibrous tissue with marked destruction of the vesicles and distortion of their lining epithelium. The integument showed cell proliferation in the epidermis, and also in the neighbourhood of the blood-vessels in the cutis vera.

Glasgow Royal Infirmary.

The opposition to the official scheme for the re-building of the infirmary on its present site has now taken definite shape. A meeting of the profession for the purpose of considering the scheme was held on the evening of April 22nd, and though some difference of opinion was expressed with regard to the exact phraseology of the resolutions to be adopted, the meeting was unanimous in condemning the official scheme in so far as it contained proposals to increase the number of beds in the infirmary. The chair was taken by Professor Gairdner, who disclaimed on behalf of the promoters of the meeting any suggestion of antagonism to the Royal Infirmary or any desire to check public liberality or to divert the money subscribed to any other purpose than the welfare of the infirmary. Their sole desire was to secure that the funds raised in connexion with the Diamond Jubilee should be used to the best public advantage. By subsequent speakers it was shown that the present site of the infirmary was already overcrowded, and that the schemes providing an increased number of beds involved the erection of buildings which in their plan and arrangement outraged all recognised principles of hospital construction. The meeting adopted resolutions to this effect, and appointed a committee to press this opinion on the executive committee dealing with the official proposals.

Medical Appointments.

The positions of Professor of Ophthalmology in St. Mungo's College, Glasgow, and Ophthalmic Surgeon to the Glasgow Royal Infirmary, are vacant in consequence of the resignation of Mr. Francis Napier, M.B., B.S. Lond.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Tuberculosis in the Dublin Dairies.

AT a general meeting of the Dublin University Biological Association held in the Museum Buildings, Trinity College, on April 8th, Dr. T. P. C. Kirkpatrick proposed the following resolution: "That this association views with the gravest concern the danger to the public health arising from the prevalence of tuberculosis among the dairy cattle, and is of opinion that vigorous efforts should be made to stamp out this disease and protect the community from this source of infection."—At a meeting of the Dublin Cowkeepers' Association, held on April 14th, the reassuring statement was made that, as the result of an examination of the city dairy cows now in progress, it was found that only four out of 1500 cows already subjected to examination were tuberculous. This examination was carried out by Dr. G. Burbridge White and Mr. Andrew Watson.

Election of Medical Officer to the Ballinasloe Workhouse.

At a meeting of the Ballinasloe board of guardians on April 14th no less than thirty-eight guardians were present, including Lord Ashtown, who was in the chair. After a closely contested election Mr. Duffy, of Kiltomer Dispensary district, was appointed.

Mater Misericordiæ Hospital, Dublin.

The medical board of this hospital has issued invitations to meet the football team at dinner at the Hôtel Métropole on Monday, May 3rd. The entertainment is being given in order to compliment the members of the clinical class constituting the football team in connexion with their recent triumph in obtaining the champion cup competed for each year by the students of the hospitals of Dublin.

Royal Medical Benevolent Fund Society of Ireland.

At the meeting of the committee of this society, held in Belfast last week, grants were made, from which it appears that the branch has given relief to the extent of £90 for the coming year. The treasurer reported a substantial increase in subscriptions in response to a circular issued to the members of the profession in Belfast. The annual meeting is to be held on May 5th.

The McGovern Hydrophobia Cure.

A curious case came before the Irish Master of the Rolls on April 24th. The guardians of the Newry Union, believing in the efficacy of the so-called "McGovern cure for Hydrophobia," in 1895 passed a resolution authorising the master of the union to take three men who had been bitten by dogs to Philip McGovern of Cavan for treatment. McGovern is a farmer and is in no way qualified as physician, surgeon, or apothecary. The Local Government Board, hearing of this, communicated with the board of guardians to the effect that the residence of McGovern was not a hospital or infirmary within the meaning of the Act 25 and 26 Victoria, Chapter 83. McGovern then applied to the board of guardians for £16 for his services to the three men and a girl who had been sent to him. The board, on Nov. 30th, 1895, deferred consideration of the payment, and in May, 1896, McGovern served them with a civil bill process for the amount claimed. The guardians decided not to enter any appearance to the action, and at the succeeding sessions a decree was granted for £16 and £1 1*s.* 6*d.* costs. A cheque was drawn by the guardians for £17 1*s.* 6*d*, but before it reached the judgment creditor the decree was executed, and certain cows the property of the guardians were seized, and the amount claimed, with a further sum of £1 8*s.* 6*d.*, was paid by the clerk to redeem the stock seized. This action of the clerk was approved of by the guardians. The auditor, however, disallowed the £4 which had been charged for travelling expenses and surcharged the special defendants. The present action, brought by the Local Government Board, claimed that the special defendants (who passed the resolution) and the Newry guardians should refund £17 1*s.* 6*d.* to the credit of the union, and that an injunction should be granted restraining the guardians from acting in pursuance of the resolutions already referred to. The Master of the Rolls gave judgment in the terms asked for.

The New Hospital for Tyrone.

At a meeting of the promoters of the new hospital for County Tyrone, held last week in Omagh, it was announced that the subscriptions amounted to £4000, and as the old building is estimated as worth £2000 this would raise the funds to £6000.

Death of the Ex-President of Queen's College, Cork.

Dr. James W. Slattery, M.A., LL.D., ex-President of Queen's College, Cork, has just died at the College. He was appointed President in the year 1890, and his appointment at the time was a matter of surprise, as he was little known to the general public. He had been educated at Trinity College, Dublin, and afterwards was admitted to the Bar. Soon after he was appointed it was found that he was suffering from diabetes and Bright's disease, and owing to his continued ill-health he was retired at the end of last year, but as he was too weak to be removed he continued to reside in the President's house up to the time of his death.

Fatal Accident at a Hurling Match.

During a hurling match in the Cork Park a player received on his neck a blow aimed at the ball with a "hurley" and died within a very short time. It was found that two of the cervical vertebræ were fractured.

April 27th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Academy of Medicine.

THREE important communications have been made to this society by M. Chipault, the distinguished surgeon who has done so much good work as regards surgical operations upon the bony coverings of the cerebro-spinal axis. In the first of these papers he gave an account of his treatment of curvatures of the vertebral column such as scoliosis and Pott's disease by means of what he terms "une planche vertébrale," to which the patient is fixed by means of straps after reduction of the deformity under chloroform. The writer finished his paper by maintaining his priority for this treatment in opposition to M. Callot, for he himself gave an account of this treatment in 1895 at the Congress of Surgery, and in 1896 asked his various friends, and especially M. Callot, to make trial of it. It would be unfair to attribute the merit of this invention to M. Callot, for he did his operations at a much later date than M. Chipault. M. Chipault's second paper dealt with sacro-lumbar puncture. He himself considered that this operation would be a great resource in the future, not only for the tapping of the cerebro-spinal fluid, so as to arrive at a diagnosis in the case of meningeal tuberculosis by the finding of bacilli, but also for the injection by this route of therapeutic serum or other fluid. He published nineteen cases, of which two were particularly interesting on account of severe syphilitic complications. The third paper had for its subject the radical cure of perforating ulcer of the foot by the stretching of the plantar nerves. In seven cases he had met with only one failure. M. Doyen, a young surgeon, has brought out a new method for the extraction of large polypoid growths in the naso-pharynx. He does not remove them by means of snares or by means of cutting them away with forceps. He examines with his finger the region behind the soft palate, and rapidly tears out the growth without being disconcerted by the enormous quantity of blood which generally flows. As soon as the polypi are removed the hæmorrhage stops of itself. M. Doyen has operated on many cases and always with success. Four papers were read upon appendicitis, but this question seems to have lost its interest somewhat. MM. Mourtier and Granier contributed a paper as to the curious effects which static electricity produces in modifications of the human voice. A singer sitting upon an isolated stool coupled to the negative pole of a static machine was made to breathe the atmosphere, which was electrified by means of a brush electrode; after a short time, and very often at the first sitting, the voice became full and clear, the quality much more agreeable, and the voice was less rapidly tired.

The Medical Congresses.

The Obstetrical Society of France has been holding its annual meeting at Paris during the Easter holidays under the presidency of M. Charpentier. Two chief subjects were debated: (1) Fibroid Tumours during Pregnancy and Labour; and (2) Repeated Abortion. As regards the first subject, M. Kaiffer read a very complete and interesting paper,

Hosted by Google

Numerous observations had been made by various members of the society. The general opinion was that the right treatment was to wait and not to intervene except in cases of extreme urgency, when operation was advised after the method of Porro.—The Congress of Learned Societies met during the same week and passed a motion that the State ought to put no obstacles in the way of either the foundation or the working of manifestations of private charity. As a matter of fact, the founding of a private hospital is almost impossible, for those wills which bequeath sums for this purpose are almost always set aside by the State either to benefit distant inheritors or itself.—The Physical Society has just held its annual exhibition, the chief objects of interest of which were those connected with the x rays. On the ground floor M. Badiguet had set up a dark room which was a veritable hall of enchantment. To the hangings were attached skeletons giving out phosphorescent rays which were wonderfully indiscreet, for despite clothing they showed up in all their nakedness the innermost depths of the spectators.

An Error of Diagnosis.

At the sitting of March 17th the Court of Appeal at Rouen gave judgment in a trial involving the responsibility of a veterinary surgeon in a case which had been submitted to him. A little girl who was seated by the side of her parents was bitten in the face by a dog. The dog, the owner of which was unknown, was promptly killed and submitted for examination to the veterinary surgeon of the district, M. Vandescal. After a post-mortem examination, which showed that the stomach of the dog was perfectly empty and that the intestine contained nothing except two tapeworms, the veterinary surgeon decided that the dog showed no symptoms of rabies. Nevertheless, some time afterwards the little girl became ill, and died, so three medical men certified, from rabies forty-two days after the accident. On account of this the parents of the child brought an action for damages against the veterinary surgeon. They argued that he was really the cause of the death of their child because he had made a careless post-mortem examination and had assured them wrongfully and so prevented them from taking the necessary measures to have the child treated at the Pasteur Institute. The veterinary surgeon denied that there was any relation between the bite and the death of the child, and that what had been taken for rabies was in reality tetanus. He brought witnesses to show that the post-mortem examination had been carefully made and that there was nothing in it by which he could have diagnosed rabies. The Tribunal of Rouen acquitted him and the Court of Appeal confirmed the judgment. The judgment showed, all the same, that there is no doubt that the dog was mad and that the child died from rabies appearing after the usual period of incubation. But it affirms that nothing was proved to show that the veterinary surgeon had failed to observe the rules of his profession or that he had made any wilful mistake. The post-mortem examination was made in the usual way and the veterinary surgeon could only give a simple and not a circumstantial report.

Obituary.

Many deaths have occurred among the medical profession. Dr. Magitot, who was the founder in France of modern dentistry and has written many important works upon the development of the teeth, died very suddenly during an attack of angina pectoris. He was a member of the Academy of Medicine and had been President of the Society of Anthropology.—Dr. Carrier of Varennes has died suddenly under very painful circumstances. He had just given one of his patients a hypodermic injection of morphia and she was sleeping peacefully. The patient's daughter, seeing her mother so quiet, thought she was dead, and cried out that the doctor had poisoned her. Dr. Carrier was seized with a fainting fit, and fell, unfortunately striking his head against the mantel-piece. He died some hours afterwards, just at the time when the patient woke up much relieved.

Murderous Attack on a Medical Man at Toulon.

In the suburbs of Toulon an abominable assault has been committed upon the person of Dr. Barnier by a Corsican named Cesarine, who had a grievance against him and who had sworn to kill him in a vendetta according to the custom of his country. Cesarine shot at Dr. Barnier in the street, wounded him slightly, and then fled. The following night he broke into his house, and finding his way to the bed-room inflicted on him many cuts with a sword and then shot him twice with a revolver. The mother and daughter of Dr. Barnier, who were attracted by the noise, also each received one bullet from the revolver. The Corsican fled, while Dr. Barnier, previously wounded, was removed to the hospital, where it was found that the facial nerve was cut and his respiration was very feeble. During the night the would-be assassin came to the ward of the hospital right up to the bed and tried to finish his work, but the other patients gave the alarm in time. The condition of Dr. Barnier is very serious. His assailant was arrested on the night of the following day after a regular fight with revolvers between himself and the police, in which he was seriously wounded in the head.

April 25th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Spread of Psittacosis.

IN THE LANCET of April 10th (p. 1058) I mentioned the outbreak of this disease in Genoa, where fourteen persons have already been attacked by it and eight have died—the last death being that of Signor Gavino, brother of the captain of the *Manilla*, in which the two infected parrots were brought from Brazil. Now Captain Gavino himself, his wife, and his daughter are under treatment for the same malady. The Uffizio Civico d'Igiene was not an hour too soon in its warning to the public against harbouring these domestic pets, as from being sporadic the broncho-pneumonia they convey has assumed almost an epidemic form. Meanwhile, the susceptibility of the parrot to pulmonary disorders—above all, to tuberculosis—is being put *en évidence* by the medical journals, most of which refer to the classic treatise on the subject by Dr. A. De Gordon y de Acorta, a physician of Havana. The malady, often hereditary in the bird, is invariably accentuated by the close confinement and the privations encountered during the voyage to Europe, where, again, even if it arrives in fair health it is for the most part exposed to insanitary conditions, under which it often contracts tuberculosis and broncho-pneumonia from proximity to human sufferers from these ailments. In Berlin the profession has long been alive to the danger of harbouring and petting the bird, the Veterinary School there having had 154 parrots under observation, and 54 of them having been found by bacteriological tests applied by Professor Eugen Fröhner to be labouring under advanced tuberculosis. The lesson, so familiar on the Continent, is worth repeating in the British Isles, where the parrot is imported from nearly every colony, tropical or sub-tropical, and where well-nigh every one of its 355 species is typically represented.

The Attempt on the King of Italy's Life.

A host of suppositions as to the motive and the mental condition of Acciarito, the would-be regicide of Thursday last, are in the air; but the "primo interrogatorio" of the police, the more its findings are considered, will suffice to reduce them to a very limited and very commonplace category. Passanante, who made the first attempt of the kind in the late autumn of 1878, was a fanatic, the victim of religious zeal. His was a form of "pazzia ragionante" (ratiocinative madness), and he believed that in striking a fatal blow at the King he was vindicating the Pope. He has been happily defined as a "Ravaillac basilisco" (an ophidian Ravaillac), and is now an inmate of the Asylum for Criminal Lunatics at Montelupo in Tuscany, where his condition in October last was described in THE LANCET[1] under the heading of the "Belva Umana" (human wild beast). But Acciarito, so far as ordinary tests can be relied on, is clearly no lunatic. One of his first admissions was that he was "affamato" (starving), and as this was succeeded by others it became more and more evident to the "judice istruttore" (Juge d'Instruction) that he had to deal with an anarchist of the now familiar type. Accomplices, indicating conspiracy, have already been found and arrested, while the lethal weapon he bore had the same insignia as that of Caserio, the murderer of President Carnot. It is of very fine workmanship and

[1] THE LANCET, Oct. 31st, 1896, p. 1273.

Hosted by Google

temper, the twisted handle having wound round it a steel wire, and on one arm of the hilt there is engraved the letter A, signifying "anarchist," and on the other a cross +, signifying death. It will not be till the first days of June that the regular trial will begin; but meanwhile the presumption seems to be almost inevitable that in Acciarito we have a replica of Caserio, whose example in avenging "himself and humanity" on the person of the "bourgeois President" seems closely followed by his Roman disciple, whose victim was to have been the "popular king." Caserio, too, was "affamato." He had not broken bread before he committed the fatal deed, and "hunger," as Acciarito remarked to the judge, "è una cattiva consigliera" (is a bad councillor). No doubt the criminal anthropologist will intervene at the trial, as he did at Caserio's, and it is well that science, even tentative science, should have its opportunity of throwing light on phenomena which are becoming all too flagrant—indeed, periodical enough to be well-nigh systematic. Coincident almost to an hour with the attempt on King Humbert there was one on the President of the Republic of Uruguay. Anarchic conspiracy, it would seem, aims at the suppression of authority in general, with a fine indifference to institutions, whether monarchical or republican. One element, I may add, in Acciarito's purview did not exist in Caserio's. Even had his deadly purpose succeeded he would not have been capitally punished—the guillotine or death by hanging having been abolished in Italian criminal law. It may be time for Italy to revise that innovation and return to the old system, just as Switzerland has had to do. Her statistics demonstrate only too eloquently of how efficacious a deterrent of homicide she deprived herself by the abolition of the death-penalty.

"Radiografia Roentgen."

The Italian schools have enthusiastically taken up the "Roentgen rays" as an auxiliary to diagnosis, treatment, and instruction—none with greater effect than the University of Pavia. Dr. Giuseppe Cattaneo, surgeon-in-chief in the Ospedale Civico of that city, having removed an entire bone from the left inferior extremity of a boy patient, thereafter placed him in the Istituto Fisico of the University, where, under the superintendence of Dr. Petinelli, were initiated, with the help of the Roentgen rays, a series of object-lessons on the reproduction of the lost bone. The organic functions of the osseous tissues as illustrated in the reproductive process were watched and registered from time to time at stated intervals by Professor Petinelli's colleagues and the University students, and the value of the Roentgen rays in surgical diagnosis and treatment, and equally in surgical teaching, was vindicated in the most striking manner. Professor Petinelli's official report of the case, supplemented by illustrations of the successive stages of the reproduced bone will be awaited with interest.

Italy at the Twelfth International Congress of Medicine and Surgery.

Strong and steady efforts are in progress to make the Italian representation at the above congress as numerous and effective as possible. At a meeting just held here, under the presidency of Dr. Baccelli, an order of the day was passed inviting delegates of the several Schools of Medicine and "Accademie Mediche" to form local committees, and establishing a "Comitato Centrale" at Rome to promote the object in view. Of this central committee the president, elected by acclamation, was Dr. Baccelli, and its secretary, Dr. Ezio Sciamanna, Professor of Neuropathology in the Roman University and Director of the Clinique for Psychiatry in the University Institute. Facilities for reaching Moscow by rail were announced on the part of the Italian and Austrian companies, while the Russian companies liberally place at the disposal of the "Congressisti" a free return ticket from the frontier.

April 25th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Sporadic Influenza.

IN an article published in the *Klinische Wochenschrift* Dr. Lindenthal states that bacteriological investigations made during recent epidemics of influenza showed that the contagion of influenza is contained in the fresh and still moist secretion of the nasal and bronchial mucous membrane. It is therefore reasonable to suppose that during the periods when the disease is not epidemically prevalent the contagion is lying dormant in the human organism, and there finds all the conditions necessary for its proliferation. Support is given to this view by the fact that the sputum of persons who have suffered from influenza, especially those who are also the subject of pneumonia, has sometimes been found to contain influenza bacilli even several months after the clinical symptoms of the disease have disappeared. Such persons may infect susceptible individuals, and in the absence of any explanation of the way in which the disease was perpetuated its origin might appear to be spontaneous and independent of previous cases. Dr. Lindenthal has made bacteriological examinations in eight cases of influenza associated with pneumonia. In all of them the bronchi were affected; the ciliated epithelium was either destroyed or elevated by pus cells into which influenza bacilli had penetrated; no bacilli were ever found in the blood. In three cases there was an induration of the pneumonic centres, the alveoli being filled with fresh connective tissue, and the peri-bronchial and peri-vascular tissues being thickened. In these centres the bacilli were few in number and were found only in the pus cells. The exudation in influenza associated with pneumonia may be purulent, fibrinous, serous, or hæmorrhagic. The influenza bacillus is chiefly characterised by being immobile, by growing exclusively on hæmoglobin culture media, and by not being stained by Gram's method.

Anæmia and Enteroptosis.

Anæmia and chlorosis are among the most important concomitants of enteroptosis, and according to Meinert chlorosis arising under such circumstances is due to irritation of the sympathetic centre controlling the formation of hæmoglobin which goes on in the spleen. Dr. Buxbaum, however, has recently published an article in the *Fortschritte der Hydrotherapie* wherein he ascribes this symptom to irregular blood distribution—namely, to what seems to be a passive hyperæmia, without change either in the total quantity of the blood or in its quality. The normal peristaltic movement of the intestine assists greatly in maintaining the circulation in its vessels. A cold hip-bath influences the distribution of the blood by its effect on the splanchnic nerve, exercised both directly and by reflex action; after a time it causes contraction of the abdominal vessels, the consequence being withdrawal of blood from the intestine and the parenchymatous abdominal organs and determination to the parts of the body which are not immersed in the water. The undue accumulation of blood in the intestine in cases of enteroptosis is brought about by the impairment of the peristaltic movement, by the relaxation of the abdominal muscles, and by the inflections of the intestine itself. It follows, therefore, that treatment should be directed to increasing the tone of the muscular layer of the intestine, and one of the most efficacious among such measures is the cold hip-bath.

The Treatment of Epilepsy and Basedow's Disease.

Nine operations involving total and bilateral resection of the cervical sympathetic nerve have been described by Dr. Ullmann. Two of the patients suffered from Basedow's disease, three from well-marked epilepsy, one from chorea, one from tumour of the brain, one from hysteria and one from progressive paralysis, the latter having an epileptic attack at the time of the operation. In both cases of Basedow's disease the exophthalmos disappeared and the goitre was reduced in size; the tachycardia ceased in the one, but continued in the other. In the three cases of epilepsy the improvement was astonishing, for the fits never recurred.

The Medical Chamber.

A meeting of Vienna medical men will be held to-day in the rooms of the Medical Society, the business being to consider whether the Medical Chamber should continue its functions or should be abolished; 325 members of the Chamber will take part in the proceedings. When the Medical Chamber was founded the profession expected that it would accomplish great things as an executive organisation of medical men, and, indeed, the prospect seemed full of promise; but, like everything in Austria that is due to the initiative of the Government, the Chamber has become a purely bureaucratic institution, unrelenting to the medical men, but indulgent to the boards. For instance, the anxiety of the Chamber to be invested with the power of cancelling the diplomas of medical offenders has not failed to arouse

Hosted by Google

general dissatisfaction among the profession in Vienna, and the party antagonistic to the Chamber denounces this extension of its powers as an unwarrantable interference with personal liberty. This protest may appear astonishing in a country where political freedom is still in its infancy, and some suggestive comments on the question are made in a letter written by a medical man to a non-medical newspaper. The substance of his argument is that in acquiring the power of cancelling medical diplomas, either temporarily or permanently, and thereby debarring a man from practising, the Medical Chamber nominally exercises no more authority than the Legal Chamber, each in its special sphere; but in reality the two cases are by no means parallel, lawyers being much less affected by this disability than medical men. To be restrained from practice is no doubt a severe punishment for a lawyer, but he has the opportunity of making an income by assisting another lawyer. A medical man, however, is helpless without a diploma, and it is unjust that the Chamber should have the power of ruining him in this way. Furthermore, in the event of the Chamber being armed with this authority, will it have the assistance of the police in preventing advice being given to patients? Medical men who have committed offences against the laws of the land, and have consequently been deprived of their diplomas by the State, forfeit public confidence, but such will not be the case with those whose diplomas may be cancelled merely for transgressing the regulations of the Medical Chamber. In my next letter I will give some account of the proceedings at the meeting.

April 25th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Malignant Syphilis treated with Spermin.

AT the last meeting of the Budapest Hospital Association Professor Schwimmer announced that he had used spermin in six cases of malignant syphilis with very good results. He had chosen for this treatment only malignant cases in which it was impossible to carry out the routine mercurial treatment on account of the patients, in spite of the usual precautions, developing marked mercurial stomatitis as soon as treatment was begun. The last patient received twenty-five injections of the organic extract, which resulted in stopping the progress of the syphilitic ulcerations. Professor Schwimmer ascribes the beneficial effects of spermin to its property of improving metabolism.

Epilepsy Treated with Ovariin.

This case was published by Dr. C. Bodon in the columns of the *Orvosi Hetilap*. The patient was a girl, aged eighteen years, who had during the last four years undergone all sorts of medical treatment without any appreciable benefit. Considering that the patient developed the disease since she began to menstruate, and that her menstruation used to be very scanty and only of one or two days' duration, though she was not suffering from any disease which might have explained the diminution of the menstrual flow; considering, lastly, that Dr. Bodon had seen several instances where the different ailments connected with the climacteric and with menstrual troubles had readily yielded to the ovariin treatment, he resolved to give the ovariin a trial in this case. Before resorting to it he kept the girl under observation for a week, no medicine whatever being given. She had during this time three typical epileptic attacks and from two to five attacks of *petit mal* daily in addition. The day before the commencement of the treatment she exhibited eighteen of these slight attacks. She was given on the first day one tabloid (Merck), the daily dose being gradually increased to eight tabloids. On the second day she had one epileptic fit, but not any more fits during the whole time that the ovariin treatment lasted—i.e., fifty days. After this date ovariin was withheld for a week and large doses of bromides were given. She thereupon had three epileptic fits. Ovariin was again resorted to, and the patient remained free from epileptic fits during twenty-two days—i.e., up to the date of publishing the cases. The slight attacks (*petit mal*), however, did not subside except at the time corresponding to menstruation. Under the influence of the ovariin treatment menstruation became more copious and was of three days' duration. Dr. Bodon concluded that the ovariin treatment should be tried in all cases of epilepsy which appear to be connected with functional troubles of the reproductive organs.

Endemic of Tetany in Budapest.

It is known that tetany may sometimes become endemic, and outbreaks of this kind have been observed in Paris, Vienna, and some other towns. Up to the present time it has only occurred sporadically in Budapest, but it would seem that the disease has lately been assuming an endemic character in this town, no less than ten well-marked cases having been notified during last week. No explanation of the endemic is obtainable.

April 24th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Medical Schools Combine.

AT a special meeting of the Board of Regents of the University of the State of New York the faculties of the Bellevue Medical College and the New York University Medical College were consolidated, and will now be known as the New York University Bellevue Hospital Medical College. The determination to consolidate the colleges was arrived at by their governing bodies on April 5th. The advantages of the scheme were so apparent to both bodies that it required but three weeks to complete the preliminary negotiations. The Council of the University on March 17th laid before the trustees and faculty of the Bellevue College a statement of the benefits, both material and educational, that would arise from uniting the two institutions. Two days later the trustees of the Bellevue College unanimously decided to transfer the direction of the college to the University on the assumption by the latter of the obligations of the Bellevue institution to the city. These obligations were formally undertaken by the Council of the University last Monday, and it only required the consent given by the regents to give effect to the consolidation. The fusion of the two schools, one of which had an enrolment of 713 students last year and the other of 344 students, will make the new college one of the largest and most important seats of medical instruction in the United States. The total faculty will number 113. The facilities and plant of the united colleges will be equal to those of some of the best equipped schools in the world. The University owns buildings covering a frontage of 130 ft. opposite Bellevue Hospital. In addition to the college premises, the Bellevue trustees possess the Carnegie Laboratory in East 26th-street, presented by Andrew Carnegie about ten years ago; also there has just been purchased by the friends of Bellevue College a frontage of 150 feet in First-avenue, adjoining the Carnegie Laboratory. These two properties together would furnish ample building room for all the purposes of a great medical college. In length of existence the University Medical College is older by some twenty years than the Bellevue College. The project of establishing a medical department was first discussed in 1838, though it was not until 1841 that the scheme took practical shape. The first faculty elected comprised Drs. Valentine Mott, Granville S. Pattison, John Revere, Martyn Payne, G. S. Bedford, and John W. Draper. It has graduated 6700 *alumni*. The Bellevue Hospital Medical College was incorporated by a special Act of the Legislature in 1861. It has 4734 *alumni* scattered through this and other countries.

Suffering from the Overflow of the Mississippi.

The enormous floods that have led to the overflow of the Mississippi River have caused an amount of suffering that renders the event a national disaster. The President has sent a special message to Congress recommending a liberal appropriation for the relief of the sufferers. These are stated on reliable authority to be the most destructive floods that have ever devastated the Mississippi valley, the water being much higher than the highest stage it has reached before. From Marion (Ark.) north of Memphis, to Greenville (Miss.), a distance of more than 250 miles by river, it is reported that there are now at least fifty towns and villages under water, and a territory extending from 100 miles north of Memphis to 200 miles south, and from five to forty miles wide, is submerged. Hundreds of thousands of acres of cultivated soil, with growing crops,

Hosted by Google

are included in the submerged territory. In this section alone there are from 50,000 to 60,000 people whose property has been destroyed and whose business has been suspended. Growing crops have been ruined, thousands of cattle have been drowned, and the inhabitants of certain areas threatened with starvation. As a great majority of the sufferers are small farmers, they have thus been left entirely destitute and will be unprepared for work, even after the floods have subsided.

Medical Inspection of the Scholars of the Public Schools.

The New York Board of Health has appointed a large number of medical men as inspectors of the children who daily attend the public schools. The object is to prevent those who have symptoms of contagious disease from entering the school, the inspection being carried out at the school-house entrance. The first day's inspection resulted as follows: 140 children were found unfit for association with their schoolmates and sent home with notes to their parents informing them of the children's condition. Among these were 14 cases of diphtheria, 3 of measles, and 1 of scarlet fever; 35 cases of contagious eye diseases, 3 of mumps, and 1 of croup; of parasitic diseases there were 55 cases in which the head was affected, and 12 of the body; and there were 8 cases of chicken-pox and 8 of other communicable diseases.

Inspection of Meats Exported from America.

The new Secretary of the Interior has issued the following Order:—"From and after March 15th, 1897, all beef offered for transportation to European ports—whether fresh, salted, canned, corned, or packed, being the meat of cattle killed after the passage of the Act under which this Order is made—shall be accompanied by a certificate issued by an inspector of the department showing that the cattle from which it was produced were free from disease and that the meat is sound and wholesome; and in order that it may be determined whether all beef exported to European ports has been so inspected and found to be wholesome, it is further ordered that the meat of all other species of animals exported to such ports which for any reason does not bear the inspection stamps of this department shall be packed in barrels, cases, or other packages, which are legibly marked in such manner as to clearly indicate the species of animal from which the meat was produced. Meat which is not so marked, and which is not accompanied by a certificate of inspection, will be classed as uninspected beef and will not be allowed exportation to European ports."

Regulation of Dispensaries.

A law of the State of New York recently made, aims to correct the abuses of out-door medical relief, by requiring that all institutions which give that relief shall be under the rules and regulations of the State Board of Charities. This board recently inspected the dispensaries of the State, and it was found that there has been in the last decade a vast increase of these institutions. In the city of New York they number 115, and their statistical returns show that nearly 50 per cent. of the whole population receive medical treatment gratuitously. The State Board of Charities is a body which under the present Act will have complete control of the methods of out-door medical treatment in the State and will have power to give and revoke licences.

April 17th.

FOOTBALL CASUALTIES.—A member of the Ashton, Cheshire, team died on the 20th ult. from abdominal injuries received in a match on Good Friday between Ashton and Halsall.—In a League Second Division match on the 24th ult., at Blackpool, a player fractured his right arm.—While playing in a match at Tividale last week the centre half-back for the Great Bridge Club, Staffordshire, a player from Horseley Heath, sustained injuries from which he died two days afterwards.—On the 26th ult., at Caledonian-park, Holloway, during a match between the London Caledonians and Tottenham Hotspur Clubs, a player (the Caledonian left wing) fractured his right leg, and was removed to the Great Northern Hospital, Holloway-road.—In the course of a match at Stockport between two factory teams, a player, a collier, sustained concussion of the brain, and was taken to the Stockport Infirmary, where he died on Tuesday last.—On the same day a youth, aged fourteen years, also died in the same infirmary from injuries received while playing in a game with other youths.

Obituary.

JOHN MAGRATH, M.D., M.S. Q.U.I., M.R.C.S. ENG., L.S.A.

DR. MAGRATH, of Forest Row, Sussex, whose death occurred suddenly from cerebral hæmorrhage on April 10th, at the age of fifty-two years, was an able and highly esteemed practitioner. His medical education was commenced at Queen's College, Belfast, and completed in 1872 at University College, London, in which year he took his M.D. degree at Queen's University, Ireland, being first in honours and gold medalist in medicine and other subjects. At the conclusion of his collegiate education he was appointed, in August 1872, resident medical officer to the East London Hospital for Children, and later assistant physician and physician to the same hospital. In 1873 he was appointed assistant physician to the Metropolitan Hospital, Kingsland-road, a post which he held for two years, and also physician to the Metropolitan Dispensary. It was at first his intention to settle in London as a consulting physician, but owing to the sudden death of a relative in 1875 he was compelled to succeed to a practice at Forest Row, near East Grinstead, where he practised until his death. Dr. Magrath was a man whose conspicuous abilities would have secured his success in any walk in life, and he rapidly won for himself the appreciation and esteem of a large circle of patients; in addition to his private practice he held until his death the post of medical officer to the East Grinstead Union and also that of medical officer to the East Grinstead General Dispensary. He was a man of large sympathies, and untiring energies, and his loss will be felt by none more keenly than the poor of the district in which he resided. Recognising the necessity of out-door recreation for the hard-worked professional man, he was one of the founders of, and became largely interested in, the Ashdown Forest Golf Club.

The funeral took place at Forest Row on Wednesday, April 14th, in the presence of a large number of mourners and friends and many others who were anxious to show by their presence their sense of the loss of an able, sympathetic, and kind-hearted medical adviser. The service at the church was conducted by the vicar, the Rev. A. J. Swainson, assisted by the Rev. E. Ruck Keene, rector of Copford, Essex, and the Rev. T. P. Bacon-Phillips, rector of Crowhurst, Sussex, the body being borne to the grave by members of the Order of Foresters.

JAMES METCALFE APPLETON, M.D. PISA, M.R.C.S. ENG., L.S.A.

DR. APPLETON was the second son of Mr. Richard Appleton, of Stokesley, Yorkshire, a country surgeon of extensive practice in Cleveland. He came of a long lineage, for he belonged to an old yeoman family which originally sprang from Appleton le Wiske, and had always lived in North Yorkshire, having for more than two hundred years farmed their own land at Newclose, Hutton Rudby. Commencing his studies at the Leeds Medical School, Mr. Appleton eventually proceeded to Edinburgh, where he was the companion of another Leeds student, whose real name was Roberts, but who afterwards, under the assumed name of Stanley, became famous as one of the naval surgeons of the *Erebus* and *Terror* in the ill-fated Franklin Expedition. Before becoming qualified to practise Mr. Appleton continued his studies in France and Italy at a time when such an undertaking was rarely thought of, and in after years he delighted in giving interesting particulars of his student life abroad, expatiating on the invariable courtesy and kindness of the great French professors of that day. In 1836 he received the Licence of the Society of Apothecaries of London, in 1837 he became a Member of the Royal College of Surgeons of England, and in 1838 he graduated as M.D. at the University of Pisa. He then settled in London, and for more than fifty years practised in Curzon-street and Half Moon-street, Mayfair. Dr. Appleton was for many years on the vestry of St. George, Hanover-square, at a time when it carried on the whole of the administration of this important parish, and was well-known as an active member, possessed of a sound judgment and considerable business ability. He died at his residence, 27, Gilston-road, South Kensington, on April 18th, aged eighty-two years.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the First Examination of the Board at the quarterly meeting of the examiners in the subjects indicated under the "Four Years Regulations":—

Part I., Chemistry, including Chemical Physics:

Anning, James John, private study.
Jones, Thomas Burnell, St Bartholomew's Hospital.
Pettigrew, William, Firth College, Sheffield.
Verity, Robert James Stanley, Charing cross Hospital.

Part II., Materia Medica:

Anning, James John, private study.
Crabtree, Emilio Fredrico, St. Bartholomew's Hospital.
Molineux, Bernard Newmarch, St. Thomas's Hospital.
Musgrove, Elward Hugh, University College of South Wales, Cardiff.
Peirce, James Arthur Lilwall, Mason College, Birmingham.
Pitts-Tucker, Francis Augustus, St. Thomas's Hospital.
Sparkes, William Moore Bell, King's College Hospital.
Wright, Louis, St. Thomas's Hospital.

Part III., Elementary Physiology:

Robinson, Ricardo Adolfo, University College Hospital.
Sowden, George, London Hospital.

The following gentlemen passed the third examination of the Board at the quarterly meeting of the examiners in the subjects indicated under the "Five Years' Regulations":—

Part I., Chemistry and Physics:

Agar, Samuel Annesley, London Hospital.
Apperley, Henry David, Middlesex Hospital.
Bachs, Johannes Adolphus, King's College Hospital.
Bailey, Charles Henry Farley, Westminster Hospital.
Bates, Joah Edward Lionel, Guy's Hospital.
Blanc, Antonio, King's College Hospital.
Boclet, Faustian Marcel, Charing cross Hospital.
Bridge, John Crosthwaite, Middlesex Hospital.
Butler, Archibald, St. Bartholomew's Hospital.
Capon, Benjamin, University College, Liverpool.
Carling, Ernest Rock, Westminster Hospital.
Clitheroe, Herbert George, London Hospital.
Darbyshire, Harold Stewart Cassam, Firth College, Sheffield.
Drinkwater, Fredrick Andrew Worsley, University College, Liverpool.
Duigan, Victor John, St. Bartholomew's Hospital.
Emerson, Herbert, St. Mary's Hospital.
Evans, David Haydn, University College of South Wales, Cardiff.
Froggatt, George Ernest, Middlesex Hospital.
Gater, Horace James, Guy's Hospital.
Gauntlett, Owen Binns, St. Thomas's Hospital.
Gleig, Percy North, Charing-cross Hospital.
Gover, Henry Arthur Sidney, St. Mary's Hospital.
Graves, Robert Kennedy Grogan, St. George's Hospital.
Hickes, Philip Lansdown, University College, Bristol.
Hosford, Alfred Stroud, University College Hospital.
Huelin, Lewis William, St. Mary's Hospital.
Hulseberg, Emile Castern, Westminster Hospital.
Inness, William James Deacon, St. Mary's Hospital.
Jackson, Frederick Douglas Selmes, Guy's Hospital.
Johnson, William Jerrold Greaves, St. Bartholomew's Hospital.
Lawrence, Charles Ernest, University College, Liverpool.
Lewis, Robert Robinson, Middlesex Hospital.
Mason, Alfred, Middlesex Hospital.
Michel, Arthur George, Charing-cross Hospital.
Moores, De La Hey, University College, Liverpool.
Newport, Harry MacGregor, Charing-cross Hospital.
Page, William Sidney, St. Mary's Hospital.
Paulin, George Alexander, Royal College of Surgeons, Edinburgh.
Penfold, Fred. Bailey, Middlesex Hospital.
Pern, Lionel, Guy's Hospital.
Phelps, Arthur Austin, Guy's Hospital.
Rahim, Bakhshi Isaac, King's College Hospital.
Ramsay, Palmer Devoy, St. Mary's Hospital.
Roberts, John Hamilton, Charing-cross Hospital and Birkbeck Institute.
Rogers, Stanley, St. Mary's Hospital.
Rudge, Frederick Henry, Bristol and Clifton Laboratory.
Rutherford, Randolph Henry Neilson, University College, Bristol.
Shields, William Thomas, University College, Liverpool.
Smale, Herbert, St. Mary's Hospital.
Smith, Herbert James, Yorkshire College, Leeds.
Soper, Arthur Waldron, Guy's Hospital.
Stevens, Warwick Alan George, Guy's Hospital.
Stewart, William Howard Edwin, Cambridge University.
Thomson, Frederic William, Firth College, Sheffield.
Tumber, Henry Shemeld, Firth College, Sheffield.
Turner, Charles Harold, St. Bartholomew's Hospital.
Ward, Joseph, Firth College, Sheffield.
Willan, George Thomas, Guy's Hospital.
Willian, Richard, University College, Nottingham.
Wood, Frederick Joseph, St. Bartholomew's Hospital.

Part II., Practical Pharmacy:

Adams, Harold Cotterell, Middlesex Hospital.
Ainsworth, Ralph Bignell, St. George's Hospital.
Allpart, Ronald Harrison, St. Thomas's Hospital.
Beard, Joseph, Firth College, Sheffield.
Bernard-Onralt, Hugh, Guy's Hospital.
Campbell, George Gunning, St. Bartholomew's Hospital.
Cawston, Albert Edward. Guy's Hospital.
Colyer, Stanley William Randolf, Charing-cross Hospital.
Davies, John, London Hospital.
Day, Charles Frederick, private study.
De Freitas, Quirino Bonifacio, King's College Hospital.
Denny, Herbert Reginald Harry, Guy's Hospital.
Devitt, Herbert Pye-Smith, St. George's Hospital
Dudgeon, Leonard Stanley, St. Thomas's Hospital.
Furnivall, Charles Hilton, St. Mary's Hospital.
Gettings, Harold Salter, Mason College, Birmingham.
Gribbell, William Ernest, St. Mary's Hospital.
Howells, Jenkins, Guy's Hospital.
Jackson, William Taylor, Owens College, Manchester.
Lewis, John Lloyd, London Hospital.
Mackie, Frederick Percival, University College, Bristol.
Michell, Ralph, Guy's Hospital.
Morgan, Charles Cyril, St. Bartholomew's Hospital.
Morgan, Lewis Wayne, University College of South Wales, Cardiff.
Nash, Percy James, Guy's Hospital.
Ross, Edward Halford, St. Thomas's Hospital.
Saunders, Leonard Dimock, King's College Hospital.
Saward, Arthur Henry Michael, Guy's Hospital.
Shields, William Thomas, University College, Liverpool.
Sladen, Reginald John Lambert, London Hospital.
Sturdy, Harry Carlile, Guy's Hospital.
Stusser, Israel, London Hospital.
Tayler, Arthur James, King's College Hospital.
Thompson, Cecil Charles Brandon, St. Bartholomew's Hospital.
Thorneley, Michael Harris, Guy's Hospital.
Thwaites, Harry, London Hospital.
Ward, Joseph, Firth College, Sheffield.

Part III., Elementary Biology:

Alvarado, Ricardo Ramon Eulojio, St. George's Hospital.
Ambrose, Arthur Joseph, Westminster Hospital.
Apperly, Henry David, Middlesex Hospital.
Ashton, John Hilton, Owens College, Manchester.
Baker, Harold Ramsey Popham, St. George's Hospital.
Bekenn, Justin James, Mason College, Birmingham.
Bennett, Francis Gray, University College Hospital.
Bent, Sidney Charles Henry, Guy's Hospital.
Bevir, George, London Hospital.
Blanc, Antonio, King's College Hospital.
Blasson, Charles John, University College Hospital.
Blunt, Thomas Edward, London Hospital.
Bridge, John Crosthwaite, Middlesex Hospital.
Brierley, Charles Isherwood, Yorkshire College, Leeds.
Bromley, James, Guy's Hospital.
Browne, George Buckstone, Guy's Hospital.
Browne, William Walker, University College Hospital.
Burges, Richard, London Hospital.
Burgess, Harold Lynch, London Hospital.
Butcher, Harry Hendy, St. Bartholomew's Hospital.
Butterworth, Rupert, St. Mary's Hospital.
Capon, Benjamin, University College, Liverpool.
Causton, Hubert Cyril, University College Hospital.
Cheese, Frederick William, St. Bartholomew's Hospital.
Cole, William Henchman, Guy's Hospital.
Cox, Clement Harlow, Mason College, Birmingham.
Cox, Ernest Alfred, King's College Hospital.
Croly, Henry Pennington, London Hospital.
Curtis, George William, University College Hospital.
Dall, Elliot Wilfred, St. Bartholomew's Hospital.
Davy, William Bradshaw, Middlesex Hospital.
Dermott, Edward James, University College, Bristol.
Douglas, Saxton Edward, Guy's Hospital.
Dudley, Edward Joseph Scott, Guy's Hospital.
Eames, Thomas Richard, Owens College, Manchester.
Evans, David Haydn, University College of South Wales, Cardiff.
Ewen, Gerald Sidney, St. Bartholomew's Hospital.
Ferguson, Lionel Cecil, St. Bartholomew's Hospital.
Froggatt, George Ernest, Middlesex Hospital.
Furnival, Henry Wallace, University College Hospital.
Gardner, Harry, Firth College, Sheffield.
Gray, William Harrington, London Hospital.
Grellet, Harold Rawdon, Guy's Hospital.
Hackney, Gordon Herbert, University College Hospital.
Harris, John Evans, Mason College, Birmingham.
Harris, Philip, St. Bartholomew's Hospital.
Hayes, George Sullivan Clifford, Guy's Hospital.
Hickes, Philip Lansdown, University College, Bristol.
Hollist, Gerald Wetherell Capron, Guy's Hospital.
Hood, Basil, Charing-cross Hospital.
Houlbrook, William Edward, St. George's Hospital.
Howell, Trevor, University College of South Wales, Cardiff.
Howkins, Cyril Henry, Mason College, Birmingham.
Hubbard, Adrian Russell Fortesque, Charing-cross Hospital.
Huelin, Lewis William, St. Mary's Hospital.
Hughes, Cecil Hugh Myddelton, Westminster Hospital.
Hughes, Edmund Octavius, St. Bartholomew's Hospital.
Humphreys, George Frederick, St. Paul's School, West Kensington.
Jiménez, Ricardo, Guy's Hospital.
Jones, Sydney Herbert, Guy's Hospital.
Keeling, Hugh Nevill, Yorkshire College, Leeds.
Latham, Thomas Jones, London Hospital.
Lawrence, Charles Ernest, University College, Liverpool.
Lemon, Charles John, St. George's Hospital.
Lewis, George Jepson, Guy's Hospital.
Lowe, George Carter, Guy's Hospital.
Lund, John Knowles, Mason College, Birmingham.
MacDowall, William MacDawall, London Hospital.
McMahon, Ernest Hammond, Charing-cross Hospital.
Major, Hugh Marcus, St. Mary's Hospital.
Marshall, Reginald Prynne, Guy's Hospital.
Mason, Alfred, Middlesex Hospital.
May, Charles Montague Neale, St. George's Hospital.
Miéville, George Christian Blake, University College Hospital.
Mills, Henry, St. Bartholomew's Hospital.

SOCIETY OF APOTHECARIES OF LONDON.—In April the following candidates passed in the subjects indicated:—

Surgery.—H. A. Belbin, Sheffield; W. F. Chrispin, Leeds; H. M. Church, McGill University; E. C. Flint, Royal Free Hospital; P. C. Maitland, Middlesex Hospital; A. F. Millar, St. Thomas's Hospital; J. C. Müller, Calcutta; J. Owen, Liverpool; M. Pantin (Section I.), Royal Free Hospital; R. W. C. Pierce (Section I. and II.), St. Thomas's Hospital; G. Renshaw, Manchester; A. W. S. Sheldon, St. Bartholomew's Hospital; and J. Spencer and H. de P. B. Veale, Leeds.

Medicine, Forensic Medicine, and Midwifery.—E. C. Flint, Royal Free Hospital; J. C. Müller, Calcutta; J. Owen, Liverpool; M. Pantin (Section I.), Royal Free Hospital; E. J. Parry, St. George's Hospital; R. W. C. Pierce (Section I. and II.), St. Thomas's Hospital; G. Renshaw, Manchester; and A. W. S. Sheldon, St. Bartholomew's Hospital.

Medicine and Forensic Medicine.—P. M. Brittain, St. Bartholomew's Hospital; A. J. Hayes, Middlesex Hospital; A. E. Seller, London Hospital; and J. M. Wood, Middlesex Hospital.

Medicine.—S. A. Stride, London Hospital.

Forensic Medicine.—A. Avent, St. George's Hospital.

Midwifery.—F. Atthill, Charing-cross Hospital; A. R. Eates, Edinburgh; G. F. May, M'Gill University; and A. P. Square, Middlesex Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—Messrs. Belbin, Brittain, Church, May, Owen, Pierce, Renshaw, Sheldon, Veale; Miss Flint and Miss Müller.

UNIVERSITY OF CAMBRIDGE.—The following candidates have satisfied the examiners in both parts of the Examination in Sanitary Science, April, 1897:—

Charles H. B. Adams, Octavius W. Andrews, Francis J. Brakenridge, George T. Cattell, Guy B. Courtney, John Donald, George G. Genge, Bertie B. Ham, Charles P. Handson, William A. Justice, John T. Leon, Frederick Pershouse, John Pringle, Frederick A. Rogers, Thomas H. Smith, and Herbert H. Woods.

UNIVERSITY OF EDINBURGH.—The following is the official list of candidates who have completed the First, Second, and Third Professional Examination, respectively, for degrees in Medicine and Surgery during March and April:—

First Professional Examination.—J. F. Alan, C. H. Allen, J. D. Anderson, Mary Anderson, A. A. Ayton, A. C. Begg (with distinction), Hubert Bishop, G. S. Blandy, V. C. de Boinville, E. S. Brett, J. M. L. Brown, M.A., G. C. Burgess, G. B. Butt, M. G. I. Cadell, Ewen Cameron, G. S. Carey, Alexander Cartner, A. W. S. Christie, R. V. Clark, M.A., H. L. Clift, V. A. P. Coghill, John Cook, W. P. Cormack, B. M. Cunningham, M. S. Dickson, T. G. B. Dodds, Henry Dodgson, A. R. Douglas, Charles Douglas, J. W. Duffus, M.A., W. A. Duncan, W. T. Dunn, J. M. Dupont, J. R. Edward, V. G. Fergusson, V. M. Fergusson, D. C. L. Fitzwilliams, B. G. Forman, A. T. Gavin, J. S. Geikie, E. M. Glanville, M. J. Gordon, A. L. Gurney, James Halliday, E. R. Henderson, C. G. Hey, C. E. P. Husband, William Hutchison, C. E. Hutson, J. P. P. Inglis, F. F. C. Jagger, E. M. G. Jayne, William Landsborough, Albert Leach, A. C. Lennie, James Lindsay, Elizabeth M'Elney, A. C. N. M'Hattie, J. H. M'Kee, D. M. M'Leod, L. A. MacMunn, Elizabeth Macroy, M. M. Meikle, William Miller, R. C. Monnington, Peter Murray, M.A., William Murray, J. F. Orr, D. E. S. Park, T. B. Paterson, M.A., W. S. Patton, J. G. Peebles, S. G. Peill, C. E. Pepper, H. G. Pesel, L. T. Price, P. C. Rayner, J. L. Rentoul, H. M. Roberts, J. S. E. Robertson, M. W. Robertson, G. A. P. Ross, L. S. Sandeman, M. S. Scott, Patrick Shaw, G. W. R. Skeen, M. W. Smart, C. W. Somerville, H. L. Spark, B. A. Spence, G. H. Steven, I. S. Stewart, C. P. Strong, G. L. Thompson, Robert Thompson, A. L. Venters, Philip Weatherbe, H. T. Wolfenden, J. H. Wrightson, and J. C. Zuidmeer.

Second Professional Examination in Anatomy, Physiology, and Materia Medica (New Regulations).—John Anderson (with distinction), R. A. J. Asbury, Harvey Baird, W. J. Barclay (with distinction), L. D. H. Baugh, J. G. Bell, H. W. Boreham, A. C. Brown, E. A. Brown, A. E. Burroughs, T. C. Caldwell, H. G. Carlisle (with distinction), L. M. Chesney, R. M. Dalziel, William Darling, Y. A. Djedjizian, C. H. Durrant, D. D. Farquharson, R. R. Fasson, David Ferrier, E. G. Ffrench, A. S. Frank, John Fullarton, A. E. Goldie, J. H. Gordon, T. B. Gornall, A. H. Griffith, A. M. de Gruchy, W. D. S. Harrison, F. J. Hathaway, J. T. P. Heatley, I. K. Hermon, James Husband, W. E. Hutchison, J. G. Jack (with distinction), John Jeffrey, S. H. Johnson, G. D. Laing, Thomas Livingstone, J. L. Louis, B. G. Macdonald, J. M. Macdonald, P. H. Macdonald, Harold Macfarlane, Robina M'Gregor, Andrew M'Kaig, W. M. Mackay, Maxwell Mackelvie, H. M. Mackenzie (with distinction), T. C. Mackenzie, George Mackie, R. C. M'Lachlan, L. Maclagan-Wedderburn, G. C. M'Leavy, Wm. Macniven, D. A. Macvean, J. F. G. Martin, James Masson, M.A., T. R. Matthews, W. W. Maxwell, G. H. Menzies, M.A., James Miller, B.Sc., James Miller, J. G. Mitchell, J. R. Munro, James Orr, E. C. Peake, A. S. M. Peebles, E. J. Peill, Arthur Preston (with distinction), T. A. Price, H. G. P. Raeburn, A. C. Renwick, T. E. Richards, Robert Ritchie (with distinction), William Rogers, Thomas Rogerson, R. M. Rowe (with distinction), Abrahim Shalaby, A. K. Smith Shand, G. F. B. Simpson, V. E. Sorapure, H. B. Sproat, W. J. Stuart, M.A., R. G. Thomson, R. R. Turnbull, N. D. Walker, C. H. J. Watson (with distinction), A. S. Whytock, and W. R. E. Williams.

Second Professional Examination in Anatomy, Physiology, Materia Medica, and Pathology (Old Regulations).—Nisar Ahmed, E. B. Anderson, J. H. Bam, F. J. H. Bateman, William Bennett, A. L. J. Branday, A. J. W. Buchanan, S. G. Champion, J. L. Davies, W. H. Dawson (with distinction), F. B. Feast, G. L. K. Finlay, J. V. Fox, W. F. Godfrey, A. D. Grange, E. I. Hudson, N. T. Kerr, John Mackenzie, C. C. Macmillan, D. J. C. Oliver, W. J. Pierce, G. H. W. Robertson, M.A., F. S. L. Rose, and I. B. Venters.

Third Professional Examination.—D. V. M. Adams, John Aloindor, James Allison, J. R. Anderson, W. N. Barker (with distinction), William Bell, H. A. S. Bird, J. M. Bowie, E. R. Branch, Stanley Branch, C. S. Brebner, R. N. Brebner, H. H. Broome, Robert Bruce, E. H. Brunt, James Burnet, M.A., John Cameron, Robert Cameron, J. A. Craig, William Craig, F. P. Crowther, Robert Cumming, E. F. Cyriax, J. M. Cuthbert, L. J. M. Deas, George Dick, R. J. Dick, W. H. Dickinson, C. H. Elmes, J. F. Falconer, E. G. Ffrench, Duncan Forbes (with distinction), A. D. Fordyce (with distinction), Charles Forsyth, A. F. Fraser, A. T. Gailletson, A. B. George, H. E. Gibbs, Robert Gibson, Dorothy Gilfillan, Andrew Gilmour, Alexander Goodall, A. M. Green, A. A. Gunn, A. G. Hamilton, James Haworth, T. E. Hincks, C. A. B. Horsford, Joseph Hunter, W. E. Hutchison, J. W. Ingles, W. J. Jones, G. R. J. King, G. de Labat, F. O. Lasbrey, E. W. Lewis, A. J. ROYAL COLLEGE OF SURGEONS IN IRELAND: FELLOWSHIP EXAMINATION.—Ambrose E. I. Birmingham, M.D., M.B., B.Ch. Irel., &c., having passed the necessary examination, has been admitted a Fellow of the College.

PRESENTATIONS TO MEDICAL MEN. — Mr. Richard Bevan, L.R.C.P. Lond., M.R.C.S. Eng., D.P.H., of Lydd, Kent, has been presented by the Brookland First Aid Ambulance Class with a silver cigarette case, suitably inscribed, in appreciation of the skill and ability with which the classes in that locality have been conducted.—A largely attended meeting of members of the Oddfellows Friendly Society and others was held on April 24th at

Hosted by Google

the Llwyngwair Hotel, Newport (Pembrokeshire), the occasion being the presentation of an address to Mr. H. Bowen Perkins, M.R.C.S. Eng., L.R.C.P. Lond., the mayor, who is leaving Newport. The chair was occupied by Dr. D. Havard, J.P. — Mr. R. Clark Newton, M.R.C.S. Eng., of Newcastle-on-Tyne, has been the recipient from the students of the ambulance class (St. John Ambulance Association), under the direction of the Horsley local centre of the Technical Education Committee, of a suitable thankoffering for his appreciated services to the class.

AT a meeting of the Bolton and District Medical Society, composed of twenty-eight members, duly convened and held at Bolton on April 22nd, Dr. Robinson being in the chair, the following motion, proposed by Mr. Jefferies and seconded by Dr. Brazil, was agreed to: "That on and after June 1st, 1897, whenever any registered medical practitioner, or any practitioner entitled to be registered (other than practitioners empowered by the Medical Act, 1886), either directly or indirectly issues, or sanctions, or takes part in the issuing of, any instrument or document which professes to empower the holder of such instrument or document to practise, or to hold themselves out as being in any way entitled to practise, any part or branch of the practice of medicine or of surgery, or of midwifery, such practitioner so doing shall, on due proof being given, be judged by the General Medical Council to have been guilty of infamous conduct in a professional respect, and his name shall be erased from the Medical Register, and any registrable qualification taken from him by the body or bodies which granted such. That the secretary forward a copy of this resolution to Sir R. Quain, Bart., President of the General Medical Council, 299, Oxford-street, London; to the medical journals; to Dr. R. R. Rentoul and the four other Direct Representatives—viz., Mr. G. Brown, 63, Charing-cross-road, London, W.C.; Dr. J. G. Glover, Highbury-place, London, N.; Dr. W. Thomson, Stephen's-green, Dublin; and Dr. W. Bruce, Dingwall, N.B."

THE CITY HOSPITAL, BIRMINGHAM. — Some extensive building operations, lasting over two years, have now been completed at this hospital, and have resulted in such important additions to, and replacement of, the old buildings, as almost to constitute a new hospital. The new buildings comprise two double-storeyed pavilions, each containing four large wards; a two-storeyed isolation pavilion containing eight small wards; an administrative block, with quarters for the staff; and a steam laundry, boiler-house, &c. Access to the upper storeys of the first-mentioned two pavilions is gained by a fireproof staircase terminating below in the open air, and thus effectually preventing any aerial communication between the two storeys. The flooring of the wards consists of polished oak blocks laid on cement concrete, that of the offices, passage, and entrance hall being of mosaic. The walls are faced with Portland cement with a dado of enamelled bricks five feet high, all corners and angles being rounded to facilitate cleaning. Each ward is heated by two double down-draught ventilating stoves, and the offices and halls by steam radiators. The lighting is by the incandescent gaslight. Each ward measures 63 ft. by 27 ft. by 12 ft., and accommodates from twelve to sixteen patients, according as it is used for acute or for convalescent cases. The administrative block contains quarters for the entire staff, there being 100 bedrooms, besides dining rooms, sitting rooms, and recreation rooms. An additional building is about to be erected, which will contain a waiting-room for visitors, a suite of "discharging" rooms, a "receiving" room, and a small bacteriological laboratory. There are no corridors or covered ways between the various buildings, communication being over macadamised roads and footpaths. A footbridge is now being built over the canal separating the Lodge-road Hospital from the branch institution (formerly the small-pox hospital) in Western-road. When this is completed the two hospitals will be worked as one institution, and together they will provide accommodation for 400 patients. All the wards are connected with the administrative block and the medical superintendent's office by telephone. The principal officers remain as before: medical superintendent, C. Killick Millard, M.D. Edin., B.Sc.; assistant medical officers, J. E. A. Chatelier, M.B. Edin.; and J. H. Murray, M.B. Lond.; matron, Miss E. Stansbie; and steward, F. R. Thorley. The architects for the new buildings are Messrs. Martin and Chamberlain, Birmingham, and the contractors are Messrs. W. and J. Webb. The estimated cost is about £35,000.

NEWCASTLE-UPON-TYNE NEW INFIRMARY.—The first meeting of the building committee was held on April 27th. Mr. Riley Lord, ex-Mayor, was appointed chairman, and Professor Philipson vice-chairman. The subscription is now £87,000.

DIPHTHERIA IN LONDON.—The tendency of fatal diphtheria in the county of London has, during the last two completed weeks, been again to increase. In the three weeks ended with April 10th the number of deaths from the disease had been 43, 41, and 23 respectively. In the next succeeding week, ended on April 17th, the deaths registered from diphtheria in London rose to 30, but even so they were 4 below the corrected decennial average for the fifteenth week of the period 1887–96. Of the 30 deaths 4 were credited to Bermondsey and 3 to Whitechapel sanitary areas. All but one were of persons aged under twenty years, and only 2 were of infants under one year. The admissions to hospital in the week were 83, against 91, 93, and 103 in immediately preceding weeks, and the number of patients remaining under treatment on April 17th was 757. Last week the registered deaths from diphtheria in London rose further to 40, and were 10 above the corrected decennial average for the sixteenth week of the period 1887-96. Hackney had 6 deaths credited to it, Chelsea and Battersea each of them 4, and Poplar and Greenwich sanitary areas 3 deaths each. The admissions numbered 96, and the cases under treatment on Saturday last amounted to 774. All the 40 deaths were of young persons aged under twenty years, and only one was that of an infant. In the outer ring in the two weeks in question the registered deaths from diphtheria numbered 7 and 9 respectively.

BEQUESTS AND DONATIONS TO HOSPITALS.—The late Rev. Francis Jacox, of Blenheim-road, St. John's-wood, London, bequeathed £1000 to Charing-cross Hospital to endow a bed to be called the "Francis Jacox bed"; £1050 to the Middlesex Hospital, to found a bed on similar terms; and £3000 to St. Mary's Hospital, Paddington, for three beds on the same conditions.—The Worshipful Grocers' Company has granted a donation of £100 to the Seaside Convalescent Hospital, Seaford.—In behalf of the New General Hospital, Birmingham, building fund Messrs. W. D. Rudder and Son and their employés have contributed 300 guineas.—The Board of Management of the Royal Hospital for Incurables, West Hill, Putney, has received £1000 from the executors of the late Mrs. Jane Lawrence.—The late Mrs. Jane Eleanor Rodgers, of Sheffield, bequeathed £500 to the Sheffield General Infirmary and £250 to the Jessop Hospital for Women.—The treasurer of the Leeds Hospital for Women and Children (new hospital with maternity department) has received £100 from the Pantomime Football Committee.— The treasurer of Guy's Hospital has received £1000 from Miss L. A. Williams, to endow a bed in perpetuity in memory of the late Henry Pratt, M.D., also £113 10*s.*, being a first instalment from the shareholders of the South-Eastern Railway Company, towards the re-endowment fund; also a donation from Mr. H. Stone of £105, and from "J. M." £100.—£700 has been added to the funds of King's College Hospital, being the proceeds of a ball organised by Mrs. Wace, wife of the rector of St. Michael, Cornhill.—The committee of the Royal London Ophthalmic Hospital, Moorfields, London, has received a donation of £100 from the Worshipful Company of Grocers towards the building fund of the new hospital; also 100 guineas from the Worshipful Company of Mercers towards the same fund; also £250 from the Worshipful Clothworkers' Company towards the same fund; and £100 from Mr. E. Speyer towards the same fund.—The Board of Management of St. Mary's Hospital, London, has received £900 from the executors of Mr. J. W. Langworthy.—The treasurer of the Metropolitan Hospital has received £120 6*s.* 8*d.* as the proceeds of the concert given at the Shoreditch Town Hall in January last. — The committee of the North London or University College Hospital has received £100, being the proceeds of a concert in aid of the funds, organised by Mrs. Frederick Roberts; also £250 from the Worshipful Company of Goldsmiths; also £200 from Mrs. Nathaniel Montefiore; also £250 from His Grace the Duke of Bedford, president of the hospital.—The secretary of the British Home for Incurables (offices, 72, Cheapside, London) has received from the executrix of the late Mrs. J. Rennie, of Anerley, £1000.—The Alexandra Hospital for Children with Hip Disease, Queen-square, Bloomsbury, London, has received a

Hosted by Google

donation of £200 from a "Lady."—The committee of the London Hospital has received an anonymous gift of £1000 for the endowment of a bed in the hospital.—Mr. E. Hildred Carlile of Helme Hall, Huddersfield, has sent a donation of £8000 to the Huddersfield General Infirmary as his contribution to the completion of the infirmary buildings and "in commemoration of Her Majesty's long reign."—Mr. John Brigg, M.P., and Mr. Prince Smith have each given 1000 guineas for providing better hospital accommodation at Keighley.—The employés of Messrs. W. D. and H. O. Wills, Bristol, have subscribed £172 towards the proposed convalescent home for Bristol.—"C. S. B. D. I." has given £100 towards the extinction of the debt of £668 on the Bristol Hospital for Sick Children and Women.—The Workmen of Sir W. G. Armstrong, Whitworth, and Co., at Elswick, have contributed to the local medical charities £557 10*s.* 6*d.* for the quarter ending March 31st last, and of this sum £413 0*s.* 8*d.* has been allocated to the Royal Infirmary, Newcastle-upon-Tyne.—The treasurers of the Middlesex Hospital have received a donation of £1050 from Mrs. Sarah Moore Thompson to endow a bed in the cancer wards to be called the "Moore Thompson" bed, also £500 from Miss Chippendale in memory of a sister.—The Baroness de Hirsch has sent to the Lord Mayor, the president of the Jews' Hospital and Orphan Asylum at Norwood, a donation of £1000 towards the fund for the new wings, and contributed £1000 in aid of the building fund for a French convalescent home at Brighton in connexion with the French Hospital in London; also £200 towards the extension and improvement fund of Queen Charlotte's Lying-in Hospital, Marylebone, London; also a donation of £300 to the North-Eastern Hospital for Children, Hackney-road, Shoreditch.—The late Colonel H. Page, J.P., of Llandaff, has bequeathed £1000 to the Glamorganshire and Monmouthshire Infirmary and £500 to the *Hamadryad* hospital ship, Cardiff.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Easter Recess.

AFTER a recess of almost a fortnight the House of Commons resumed its session on Monday, April 26th. The House of Lords will resume on Monday, May 3rd.

Public Burial Grounds.

Mr. J. W. Sidebotham intends to move for a select committee to inquire into the subject of burial grounds provided by local authorities, whether any alterations in the law are necessary, especially in regard to the consecration of the ground, the provision of chapels, the allocation of fees, and the appointment of chaplain.

HOUSE OF COMMONS.

MONDAY, APRIL 26TH.

Army Medical Department.

Mr. Bartley asked the Under Secretary of State for War whether it was a fact that the effective branch of the Army Medical Department was, and had been for some time, much below its authorised strength; whether the cost of the non-effective branch of the Army Medical Department was now nearly equal to, if it did not exceed, the cost of the effective branch; whether he was aware that many of the medical officers who now retired on a pension at the early age of about forty-five years were willing to remain on the active list; and whether he would take steps to retain on the active list medical officers who now retired in the prime of life, but who were willing to remain on the active list.—Mr. Powell Williams, who replied for the Under Secretary, said it was the fact that the numerical strength of the Army Medical Department was, and had been, about forty below what was authorised. The non-effective charge was only one-half the effective charge for medical officers. At forty-five years of age medical officers retired voluntarily, but they were required up to fifty-five years to come up for service if an emergency arose.—Dr. Farquharson asked whether it was not the case that medical officers were not compelled to retire before the age of fifty-five years?—Mr. Powell Williams replied that those who retired at forty-five years did so voluntarily, but all who retired at that age were liable to come up for service if an emergency arose.

Overcrowding on the Underground Railway.

Mr. Weir asked the President of the Board of Trade whether, having regard to the excessive overcrowding of the carriages of the Metropolitan and Metropolitan-District Railways, he would suggest to those companies that the by-law approved by the Board of Trade under which a passenger was liable to a fine for travelling in a carriage of a class superior to that for which he was booked should be relaxed when he was unable to find a seat in the class of carriage for which he had taken a ticket.—Mr. Hanbury replied, saying that the President of the Board of Trade was not prepared to make the suggestion referred to in the question to the railway companies, as he doubted if it would act as a remedy for overcrowding. As a matter of practice the Board of Trade understood that the companies did not prosecute except in clear cases of intent to defraud.

TUESDAY, APRIL 27TH.

Medical Inspectorship of Prisons.

Mr. Pickersgill asked the Secretary of State for the Home Department whether Dr. Gover had resigned the medical inspectorship of prisons, and, if so, whether he would take the opportunity to appoint a medical man to be a member of the Prisons Board in accordance with the recommendation of the late Committee on Prisons, and thus assimilate the constitution of the Prisons Board in England to that of the Prisons Board in Ireland.—Sir Matthew White Ridley, in reply, said it was the case that Dr. Gover had resigned his appointment, but he had already decided, after giving full consideration to the recommendation of the Prison Committee, that it was not possible to dispense with the services of a medical inspector, and had therefore appointed Dr. Smalley, the medical officer of Parkhurst, in succession to Dr. Gover. This did not of course determine the question of the appointment of a medical member of the Board, but he did not at present contemplate making any such appointment.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

Sydney Hall Fleming, Vicar of St. James, Croydon, uncle of the bride, Berthon F. Pendred, M.R.C.S., L.R.C.P., youngest son of Vaughan Pendred, C.E., of Crohill, Streatham, to Eleanor, eldest daughter of Francis Henry Fleming, of Haslemere, Streatham.

PENNY—MACRAE.—On April 24th, at St. John's Church, Upper Norwood, Alfred Gervase Penny, M.A., M.B., B.C., of Peterhouse, Cambridge, and St. Bartholomew's Hospital, to Nellie Grace Gillanders, eldest daughter of late John MacRae, of Arrowah, Bengal.

SLATER—LOY.—On April 22nd, at Whitton Church, near Ludlow, Leonard Slater, M.A., M.B., of Osman House, Fortis-green, London, N., to Agnes, youngest daughter of the Rev. James Loy, Rector of Hardenuish, Wilts.

SOUTHERN—DUNLOP.—On April 21st, at St. Columba's Church, Pont-street, Belgrave-square, London, John Acton Southern, M.B., to Elizabeth Lillias Mary, eldest daughter of the late William Carstares Dunlop, of Gairbraid.

SPARROW—HUGHES.—On April 22nd, at St. Thomas's, Shepherd's-bush, Staff Surgeon Horatio Septimus Richard Sparrow, R.N., H.M.S. *Medea*, fourth son of the late Dr. R. Pennington Sparrow, of Southsea, to Christian Stirling, second daughter of Charles H. Hughes, of Shepherd's-bush.

TORNEY—WOODROW.—On April 21st, at the Skipton Parish Church, Richard Hastings Torney, M.B., Bungay, Suffolk, to Jessie Gunn, youngest daughter of the late John Woodrow, of Sandywood House, Keighley.

WRIGHT—CORRIE.—On April 22nd, at All Saints', Margaret-street, by the Rev. H. C. Wright, of Haileybury College, brother of the bridegroom, assisted by the Rev. Lord Victor Seymour, Rector of Carshalton, Walter Southey Wright, B.A., M.R.C.S., &c., of Park View, Carshalton, youngest son of the late John Freeman Wright, M.R.C.S., &c., of Seymour-street, Portman-square, and of Mrs. Wright, The Hermitage, Shirehampton, to Caroline Maude, younger daughter of B. Corrie, Esq., late R.N., and granddaughter of the late Rev. Frederick Chapman and the Hon. Louisa Yelverton.

WRIGHT—PORTUS.—On April 22nd, at St. Martin's-in-the-Fields, London, by the Rev. Wm. Ball Wright, uncle of the bridegroom, Robert Ball Wright, L.R.C.P. and S. I. of Chester, third son of the late Robert Ball Wright, B.A., J.P., of Foulksneeth Castle, co. Kilkenny, to Dorothea, third daughter of the late George Bullock Portus, of N. Wales.

DEATHS.

ANDREW.—At Tavistock, Devon, James Andrew, M.D. Oxon., Consulting Physician to St. Bartholomew's Hospital, aged 67 years.

APPLETON.—On Easter Day, at Gilston-road, South Kensington, James Metcalfe Appleton, M.D. Pisa (1838), M.R.C.S., Eng. (1837), L.S.A. (1836), aged 82.

DIMSEY.—On April 21st, Alfred Dimsey, M.B., B.S. Lond., of 4, Crouch Hall-road, Crouch-end, N., late House Physician and House Surgeon at University College Hospital, aged 25.

EVES.—On April 26th, at Brooks Lodge, Cheltenham, Charles Thick Eves, Deputy-Surgeon-General, late Indian Service, in his 69th year.

LAWSON.—On April 23rd, at Hay, New South Wales, Thomas Lawson, M.B., C.M., of Dean-terrace, Edinburgh, aged 31. By cable.

ROGERS.—On April 23rd, at his residence, Holland-road, Kensington, W., George Goddard Rogers, M.D. St. And., M.R.C.P. Lond.

TEALE.—On April 19th, John William Teale, M.A. Oxon., F.R.C.S., of Scarborough, aged 58 years.

WILSON.—On April 27th, at Huntly, Aberdeenshire, George Wilson, M.D., in his 86th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (3rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (5th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (6th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.). St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.)

FRIDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (8th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (3rd).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-square, W.C.).—8 P.M. Communications by Mr. J. F. Colyer, Mr. W. R. Humby, and Mr. H. Baldwin. Exhibition of a Series of Lantern Slides by Mr. C. S. Tomes.

TUESDAY (4th).—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Parkes Weber: General Lymphadenomatosis of Bones.—Dr. Rolleston and Mr. E. L. Hunt: Dermatitis Maligna.—Dr. A. Latham: Peculiar Specimen of the Vermiform Appendix.—Dr. G. F. Still: Gumma of the Spleen in Children.—Dr. R. H. Fox: Rupture of the Heart.—Mr. S. G. Shattock: Mucosal Cysts in the Stratum Granulosum. Card Specimens:—Dr. Parkes Weber: Tight-lacing Liver in a Man.—Dr. Rolleston: Non-infective Aneurysms of Cardiac Valves.

WEDNESDAY (5th).—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Mr. J. Bland Sutton and Mr. J. H. Targett, (both with Lantern Demonstrations). Papers:—Dr. T. Wilson: Chronic Axial Rotation of an Ovarian Cyst giving rise to extreme Twisting of the Elongated Uterus.—Mr. J. W. Taylor: On a Second Case of so-called abdominal or Ventral Pregnancy at Full Term, Operation at the Twelfth Month, Removal of Child and Placenta, Recovery.

THURSDAY (6th).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-street, Cavendish-sq., W.).—8.30 P.M. Clinical Evening. Mr. P. Smith: Ophthalmic Specimens mounted in Formol Solution.—Mr. Eve and Dr. F. J. Smith: Case of Obstruction of the Cavernous Sinus.—Mr. Hartridge: Unusual (Congenital) Defect of Crystalline Lens.—Mr. E. Clarke: Three Specimens of Detachment of the Retina.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (3rd).—LONDON SCHOOL OF MEDICINE FOR WOMEN (30, Handel-street, Brunswick-square, W.C.).—6 P.M. Dr. P. Manson: Malarial Fever.

TUESDAY (4th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—Dr. Beevor: Lecture.

WEDNESDAY (5th).—HOSPITAL FOR CONSUMPTION, &c., (Brompton).—4 P.M. Dr. Mitchell Bruce: Enlargement of the Heart with Cases to illustrate its different Forms in Lung Disease, Valvular Disease, Renal Disease, and Graves's Disease.

LONDON SCHOOL OF MEDICINE FOR WOMEN (30, Handel-street, Brunswick-square, W.C.).—6 P.M. Malarial Fever.

THURSDAY (6th).—ROYAL INSTITUTION.—3 P.M. Prof. Dewar: Liquid Air as an Agent of Research.

SOCIETY OF ARTS.—4.30 P.M. Surgeon-Major Sir G. Scott Robertson: Kafiristan, its Manners and Customs.

FRIDAY (7th).—EAST LONDON HOSPITAL FOR CHILDREN.—3 P.M. Mr. R. W. Parker: Demonstration on Surgical Cases.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—Dr. Colman: Lecture.

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

CRIME IN GLOUCESTERSHIRE.

THE report of the Chief Constable of Gloucestershire for 1896, which has been recently issued, states that the total number of crimes reported to the police under the head of indictable offences was 610, being a decrease of 19 as compared with 1895. The number of persons apprehended and summoned for these offences was 658, an increase of 61 compared with the previous year's return. Of these, 440 were tried summarily—159 were discharged and 281 were convicted—96 were committed for trial and sent to prison, 37 were bailed for trial, and 85 otherwise disposed of. For non-indictable offences 1247 persons were apprehended and 5590 summoned, an increase of 536 as compared with 1895.

Mr. James Brown.—The conclusions are too sweeping and quite unscientific. We should like to have the details of some of the successful cases, with the notes of the medical men in attendance.

"WANDERING RASH OF THE TONGUE."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Nov. 21st, 1896, you have a short notice of an article by Dr. J. L. Goodall under the above heading. I have a case which defies all treatment I have brought to bear on it. Will you kindly inform me, either through your readers or by reference to any work, as to the treatment of this troublesome condition. Thanking you in anticipation, I am, Sirs, yours truly,

April 27th, 1896. SAM. T. LORD, M.R.C.S. Eng., L.R.C.P. Lond.

MEDICAL APPOINTMENTS UNDER THE LOCAL GOVERNMENT BOARD.

Quæsitor (1) will find in "Whitaker's Almanack," under the heading of Government Offices, the names of those attached to the medical staff of the central health departments of the United Kingdom, and in the Medical Directory will be found a list of the medical officers of health to the several sanitary areas of England, Scotland, and Wales. From the same source may also be ascertained the answers to queries 2 and 3. Nos. 4, 5, 6, and 7 may be answered collectively. Without a diploma in Public Health the chances of a medical practitioner who enters the Public Health Service at the present time are not good, and if our correspondent will refer to Section 18, Sub-section 2, of the Local Government (England and Wales) Act, 1888, he will find that a D.P.H. is almost a necessity for anyone wishing to win one of the higher posts, and practically the same conditions obtain in Scotland. In Ireland the state of affairs is somewhat different, but the prospects, even with a D.P.H., are not very promising. An M.D. would certainly improve his chances by taking the D.P.H., but it is necessary to point out that much would depend upon his experience, and, as regards the future, upon his age. The F.R.C.S. would be of but little special value in the service. Probably our correspondent would find that the Local Government Directories, which may be obtained from Messrs. Knight and Co, 98, Fleet-street, London, would afford him some useful information.

J. C. R. (Swindon).—There is not a fixed fee in such cases, but a fee of one guinea in the circumstances mentioned is both reasonable and usual. In the case of certifying lunatics for removal to an asylum the amount of the fee rests with the lunacy justice, but for certifying persons of unsound mind for detention in the workhouse, Section 24, Sub-section 5, of the Lunacy Act, 1890, enacts that "*the guardians* ..... shall pay such reasonable remuneration as *they think fit* to the medical practitioner who, not being an officer of the workhouse, examines a person for the purpose of a certificate under this section." If our correspondent had no previous understanding with the guardians as to what is "reasonable remuneration" he would do well to accept their offer. The only alternative is to sue the guardians in the county court, and this would probably cost more than the matter is worth, and the issue is doubtful, as it clearly rests with the guardians to fix the remuneration, and perhaps they think that some reduction should be made in consideration of the number dealt with at one time.

Mr. C. Williams.—The best way is to consult a list of charitable institutions, such as Burdett's, and to write to the secretaries of two or three for information as to rules, terms, &c.

WANTED A HOME FOR AN IMBECILE BOY.

To the Editors of THE LANCET.

SIRS,—I should be glad to hear of a place where a lad aged about twelve years, and strong in health, though of deficient intellect, could be received and taught. About 10*s.* or 12*s.* a week could be paid for him.

I am, Sirs, yours faithfully,

Wigston Magna, Leicester, April 17th, 1897. A. N. BARNLEY.

P. G. P. (Highbury).—Our correspondent will find a long list of inebriates' homes in Burdett's "Hospitals and Charities." Very few, however, take male patients, and in those that do the lowest fee appears to be two guineas a week.

MEDICAL ATTENDANCE ON THE POOR IN BELGIUM.

THE miserable payments made by local Poor-law authorities in Belgium for medical attendance on paupers have recently formed the subject of somewhat sarcastic remarks in Parliament, from which it would seem that while the usual amount expended on medical attendance, including medicines, by the different boards in the Province of Flanders rarely exceeds a penny per person annually, and in one commune is as low as a farthing, a third of a penny being quite a common rate, a certain typical society in Ghent, composed entirely of healthy men, finds its medical and pharmaceutical expenses amount to about two shillings per head. Again, the horses in the army are supplied with veterinary attendance, at an expense to the nation, which it does not think of grudging, of eighteen shillings. Of course, the comparison between a horse and a human being is not quite fair from a pharmaceutical point of view, but it is always a little tantalising to see contracts given out at fifteen shillings or a guinea per horse to a veterinary surgeon by the same authority that pays its medical officer £50 or £60 for attendance on several hundred poor people, many of whom are chronic invalids and in a condition which, if it existed in a veterinary patient, would lead to a very early interview with the knacker. The Belgian cavalry horses, it will be seen, cost as much to keep in health as is allowed for 900 poor people in some places!

LIFE-SAVING SOCIETY (ANNUAL REPORT, 1895-6).

THIS report contains many interesting features. Among these we may mention in particular an article on Instruction in Swimming at School from the pens of the honorary secretaries of the society, Mr. W. Henry and Mr. A. Sinclair, which shows the use of having a swimming drill on land. The report also gives all the names of persons who have won the society's medallions and certificates during the past year. These awards have greatly increased during the twelve months, while we are also informed that over 2000 persons have acquired a thorough technical knowledge of the various means of saving life from drowning since the work of the society was begun.

Senex.—We do not think that a correct interpretation of the results of analysis can be arrived at without some knowledge of the source of the water and of the possibility of contamination. We attach, also, among the factors which are furnished by chemical analysis some importance to the amount of oxygen absorbed. It is obvious that, although a water may not be polluted with animal matter, yet vegetable pollution may assume an objectionable proportion.

E. H. (Derby).—We never recommend individual practitioners. Our correspondent must consult his own medical man.

"MEN SHALL INCLUDE WOMEN," &c.

To the Editors of THE LANCET.

SIRS,—Your article upon the new Sanitary By-laws for London has set me reading them. I find that all the provisions suppose the persons executing the work to be of the masculine gender. Those who drafted these by-laws have overlooked the possibility of that amorphous precipitate, "the new woman," being thrown down upon the building trade. The position of some unfortunate sanitary inspector unprovided against such a contingency, when suddenly confronted with some defiant specimen of her class, would be suggestive of the roadside toll collector, who, having demanded twopence from two ladies in a dog-cart, and pointed out the by-law that the charge for a man and horse was twopence, was ordered to stand aside as they were two girls and a mare!

I am, Sirs, yours truly,

April 27th, 1897. AN OLD MAN.

Dr. Cafferata.—We do not insert such notices or approve of their publication in the lay journals, such a course being contrary to the code of ethics which governs the medical profession in this country.

A HANDSOME GIFT.

THE *Maryland Medical Journal* states that Dr. Nicholas Senn has purchased the enormous library of the late Professor Du Bois-Reymond, of Berlin, and has presented it to the Newberry Library of Chicago.

Mr. C. Simpson.—Our correspondent had better consult a local medical man and avoid unqualified "specialists."

MEDICAL MEN AND THE TUBERCULIN TEST.

AT a meeting of the Brighton and Sussex Medico-Chirurgical Society the following resolution was passed without dissension after an exhaustive discussion: "That preference should, in the opinion of this society, be given in obtaining milk supplies to such farmers and dairymen as guarantee that their cows have been properly subjected to, and have failed to react to, the tuberculin test for tuberculosis."

C. F. W.—Yes, the name and qualifications mentioned do appear in the current Register.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Dundee Courier, Derbyshire Times, Huddersfield Examiner, Sheffield Telegraph, Somerset County Herald, Norfolk Chronicle, Times of India, Hull Daily News, Pioneer Mail, Surrey Comet, Richmond Times, Scotsman, Sussex Daily News, Manchester Guardian, Builder, Kentish Gazette, Newbury Weekly News, Lichfield Mercury, Architect, Liverpool Daily Post, Luton Reporter, Wolverhampton Chronicle, Coventry Times, Yorkshire Post, Hastings Times, Glasgow Evening News, Birmingham Gazette, Midland Counties Express, Leeds Mercury, Wigan Examiner, Western Morning News, Portsmouth Times, Halifax Guardian, Salisbury Journal, Bristol Mercury, Walsall Advertiser, Birmingham Daily Post, Isle of Wight Times, Family Doctor, Cumberland Advertiser, Sanitary Record, Cambria Leader, Weekly Free Press and Aberdeen Herald, Reading Mercury, City Press, Surrey Advertiser, Hertfordshire Mercury, Citizen (Gloucester), Local Government Chronicle, Derbyshire Courier, Mining Journal, Gloucestershire Chronicle, Local Government Journal, Richmond and Twickenham Times, Health News, Transvaal Critic, Irish Daily Independent Herald, Standard, Melbourne Evening Telegraph, Dublin Sportsman, Burton Evening Gazette, West Middlesex Herald, The Morning, Daily Record, Canterbury Times, &c., &c.*

A Clinical Lecture

ON

THE SURGICAL TREATMENT OF RELAPSING APPENDICITIS, WITH A REPORT OF THREE SUCCESSFUL CASES.

Delivered at the General Hospital, Birmingham, on Jan. 27th, 1897,

BY GEORGE HEATON, M.B.OXON., F.R.C.S.ENG.,

HONORARY SURGEON TO THE HOSPITAL; SURGEON TO THE BIRMINGHAM AND MIDLAND COUNTIES HOSPITAL FOR SICK CHILDREN, ETC.

GENTLEMEN,—Inflammation of the vermiform appendix, or, as it was formerly termed, perityphlitis, is a disease from which in the majority of cases a patient suffers once, and once only, in a lifetime. He has an attack—severe or mild as the case may be—and if, under proper medical care and treatment, he is restored to health his appendix in the majority of cases gives no further trouble. But in a certain number of cases, the sequence of events is not so happy. After an interval, it may be of months or of years, a relapse occurs, and this is followed at longer or shorter intervals by a number of other ones varying much in severity. These may be so frequent and so severe as to render the patient a confirmed invalid even if he does not actually die in one of them. Relapses are, I fancy, more frequent than is generally deemed to be the case. Hospital patients, from whom most of our statistics on such subjects are derived are a very wandering population, especially in our big cities, and for this reason it is very difficult to obtain an accurate knowledge of the after history of our patients or to determine the actual percentage of relapses after apparent cures. Hawkins[1] from an analysis of 250 cases admitted into the wards of St. Thomas's Hospital found that in 23·6 per cent. there was a history of one or more previous attacks. These figures show that the percentage of relapses after apparent cure of appendicitis is certainly as high as 23 6 per cent.; and inasmuch as amongst these 250 cases are included cases which, though suffering on admission from a first attack, may possibly, after apparent recovery and discharge from hospital, have had other attacks, the percentage of relapses is probably considerably higher. In almost all these relapsing cases it is the appendix itself which is the starting-point of the recurrent attacks of inflammation. In one or two exceptional cases only have they been traced to ulceration in the cæcum itself. The principal morbid conditions which are found may be grouped under six heads: (1) an enterolith is imprisoned in the appendix (as in Case 1) with occasional distension of its blind end with pus; (2) the appendix is surrounded by dense, inflammatory adhesions enclosing an encapsuled abscess; (3) the lumen of the appendix is destroyed by ulceration and its distal end is distended with mucus or pus; (4) the appendix is coiled upon itself or acutely "kinked" and fixed in this position by adhesions; (5) the appendix is free but much thickened, resembling a mass of cartilage rather than a mucous tube (such an appendix is occasionally lengthened and unequally distended along its length); and (6) the appendix is surrounded by dense old adhesions, matting it to the cæcum, small intestine, bladder, rectum, or the abdominal wall.

In some cases these relapses seem to become milder, in others more severe as time goes on; but a severe or even fatal relapse may follow a succession of very mild ones, and we cannot predict with any certainty the character of future relapses from that of the previous ones. For this reason the principle of treatment by removal of the offending organ during a quiescent period, which has been so ably advocated, and so successfully carried out, by Mr. Treves in this country, cannot be too strongly insisted upon. But I would go still further and make it a rule to strongly advise operation in all cases where there has been a single relapse after the primary attack. Careful dieting and medicine with prolonged rest in bed may in a few of such relapsing cases effect a lasting cure, but this is the exception, and in the majority of cases relapse follows relapse, producing in some cases a chronic state of invalidism, while each relapse adds to the difficulties and dangers of any operation which may ultimately have to be performed. In my own experience during the last few years I know of five cases in which a sudden fatal general peritonitis has followed the repeated warnings given by a succession of mild relapses and in which, had this treatment been adopted and the removal of the diseased appendix been effected after one of the earlier mild attacks, these lives would in all probability have been saved.

The operation itself is often extremely simple; in the first two of my own cases it was so; but it may, on the other hand, be one of extreme difficulty. I have more than once assisted at cases where, owing to the dense and extensive adhesions, and the intimate adhesion of omentum, intestine, and cæcum, it has been found quite impossible even to expose the appendix, and the attempt has had to be abandoned. The mortality, however, attending it in skilled hands is extremely small (Mr. Treves has published a brilliant record of 150 cases with only one death). The repeated attacks of inflammation have fortunately rendered the peritoneum both less vulnerable to injury and less absorbent of poison; and for this reason an amount of tearing and bruising which, with a normal peritoneum would almost certainly set up the most intense inflammation is frequently followed by little or no disturbance. Whenever possible the stump of the appendix left after removal should be provided with a serous covering. With this object in my two first cases I raised a circular flap of peritoneum only from the appendix, commencing some half an inch beyond the point at which it was intended to excise it. The muscular and mucous coated were then ligatured with silk, cut through, and the stump touched with pure carbolic acid. The flap of serous membrane was finally stitched over the stump so as to completely cover it in. It was impossible to do this in Case 3, and I am disposed to attribute the localised suppuration which occurred to an infection of the wound from the exposed mucous membrane. No drainage of the peritoneum is necessary in uncomplicated cases. It should be avoided if possible, as the liability to a subsequent yielding of the scar and formation of a ventral hernia is thus considerably lessened. The rapid gain in weight and flesh and the quick restoration to robust health after the operation is one of its most remarkable features.

CASE 1. *Relapsing appendicitis; removal of appendix after the fourth attack; recovery.*—The patient, a man aged nineteen years, came under my care at the General Hospital on March 19th, 1896, with slight tenderness in the right iliac fossa. His first attack—the most severe one—was five years previously, the second three years, the third six months, and the fourth, whilst at the Jaffray Hospital, one month previously to his coming under my care. The attacks usually lasted about a week or ten days, and were accompanied by some pain and tenderness in the abdomen and a slight rise of temperature. He had never been sick during an attack. The last one was brought on by eating an apple. His condition on admission was as follows. He had no pain, but there was some slight tenderness in the right iliac fossa, On palpation a well-defined mass could be felt about the size of a walnut. It was situated two inches from the right anterior superior iliac spine, along a line drawn from that point to the umbilicus. Operation was performed on March 14th. The abdomen was opened by a linear incision over MacBurney's point. The appendix was found to be surrounded by matted omentum. This was separated and removed. The appendix, which was bound down and twisted on itself, was then separated from its adhesions and its mesentery was ligatured and cut through. A circular flap of serous coat only was raised for about half an inch near its junction with the cæcum. This was turned back, a silk ligature was tied tightly round the muscular and mucous coats, and the appendix cut away. The stump was touched with pure carbolic acid and the serous flap was then stitched over it with a continuous catgut suture. A small drain of iodoform gauze was left in the abdominal wound for twenty-four hours. The wound united by primary union save where the drain had been. His temperature did not reach 99°F. Some three weeks after the operation he had for about ten days some pain and frequency of micturition and a slight elevation of temperature, which with rest and low diet passed off. He

[1] Hawkins: Diseases of the Appendix, p. 112.

Hosted by Google

was discharged well on May 4th. When seen in December, 1896, he had some tendency to a small ventral hernia at the seat of the scar, and was ordered an abdominal belt. He had no more pain or abdominal trouble. With regard to the condition of the appendix, it was enlarged and thickened throughout its whole length. In its middle third it was distended into a tense sac, which on opening contained a little muco-purulent fluid and a hard oval-shaped enterolith. The coats of the appendix on section showed evidence of chronic inflammation, which was most marked in that part of the tube where the enterolith lay impacted.

CASE 2. *Relapsing appendicitis; removal of appendix after the seventh attack; complete recovery.*—A lady, aged twenty-eight years, was seen in consultation with Mr. Turner. She had had seven attacks, varying in severity, during the past four years. The present one began seven weeks previously with vomiting and pyrexia. She had been an invalid in bed ever since with occasional pyrexial attacks and exacerbations of pain in the right iliac fossa. The tumour could be plainly felt in the position of the appendix and was tender on palpation. She had lost flesh considerably. Operation was performed on Oct. 16th, 1896. The abdomen was opened by an oblique incision (as for a right inguinal colotomy). The appendix was found to be elongated and much thickened. There were no adhesions around. A circular flap of peritoneum was raised from it about half an inch from its junction with the cæcum. The muscular and mucous coats were ligatured with silk and the organ was removed after its mesentery had been ligatured with several interlacing silk ligatures. The stump of the appendix was touched with pure carbolic acid and the serous coat stitched over it with a continuous suture of fine catgut. The abdomen was closed. Primary union of the wound ensued. The patient has lost all her pains and has been perfectly well since.

The following microscopic report by Dr. Stanley relates to the condition of the appendix. Section through the appendix showed considerable thickening of, and deposit of fibrous tissue in, the peritoneal surface, with formation of new vessels. The muscular coats were also thickened and there was increase of the interstitial fibrous tissue. The mucous coat showed a form of degeneration of the epithelium and sub-epithelial cells into a series of cells having an epithelioid character and forming a fairly thick layer. In this layer the Lieberkühn follicles and solitary glands were embedded. This cellular layer was covered by cylindrical epithelium which was somewhat retrograde in type, being less well-defined than normal and the cells being irregularly shaped.

CASE 3. *Relapsing appendicitis; removal of the appendix after the seventh attack; recovery.*—The patient was a thin, delicate-looking boy, aged six and a half years. He was admitted into the Children's Hospital on Nov. 26th, 1896, suffering from appendicitis. With regard to the history, he had had six previous attacks similar to the present one, but increasing in severity, during about thirteen months. This attack began fourteen days before admission with sudden severe pain in the right groin with acute tenderness and fever. Until these attacks commenced he was strong and healthy; he had been gradually getting thin and weak since. On admission to hospital he lay with his right thigh flexed on the abdomen and complained of much pain in the right iliac fossa. There was a hard, oval, tender swelling to be felt about two inches below, and to the right of, the umbilicus. The bowels were constipated, and the tongue was dry and furred. Under rest in bed the tenderness became less, and though he vomited occasionally he improved somewhat in general health. The swelling became slightly smaller. An operation was performed on Dec. 8th. The abdomen was opened in the right iliac fossa just external to the mass. The intestine was found adherent to the abdominal wall. The appendix was coiled upon itself and distended into a hard spherical lump. This was with difficulty separated from the parietal peritoneum and omentum. It was ligatured with silk at its junction with the cæcum and excised. The stump was touched with pure carbolic acid. The abdominal wound was closed. His temperature remained normal after the operation, but his pulse continued somewhat high, varying from 100 to 120, and he vomited slightly on two occasions. On the third day the wound was dressed, and on inserting a small probe about half an ounce of fæcal-smelling pus escaped. A small drainage-tube was put in. By Dec. 14th all discharge had ceased, the tube was removed, and all stitches were taken out. On the 20th the wound was soundly closed and the patient was beginning to increase in weight. He remained an in-patient until Jan. 20th, 1897, when he was discharged, having quite regained his old weight and colour, and his bowels acting well daily. With regard to the appendix, it was distended in its middle third into a sac, which contained a hard fæcal concretion firmly wedged in it. The distal portion of the appendix was contracted and acutely twisted back upon, and adherent to, the dilated portion. The whole organ was adherent to the coats of the small intestine and the abdominal parietes.

ILLUSTRATIVE CASES OF APHASIA.

BY BYROM BRAMWELL, M.D., F.R.C.P. EDIN., F.R.S. EDIN.,

PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY, LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE, SCHOOL OF MEDICINE, EDINBURGH, ETC.

(*Continued from p. 1143.*)

CASE 11. *Sudden cerebral attack after confinement; absolute deafness to all sounds for sixteen days; temporary motor aphasia and word-blindness; absolute word-deafness for four weeks; rapid recovery from the motor aphasia; partial recovery from the word-blindness; very slow and imperfect recovery from the word-deafness; slight paraphasia and slight paragraphia; echo speech; retention of the power of writing from dictation and of reading aloud; no hemianopsia; re-development of acute cerebral symptoms (meningitis or cerebritis) six months after the original attack; hyperpyrexia; death; no necropsy.*—This case, which is the most striking example of word-deafness without total aphasia which has come under my own notice, presents many points of interest and importance. It is very unfortunate that there was no post-mortem examination; but there can be little or no doubt that the lesion was entirely, or almost entirely, confined to the auditory speech centre or the afferent tracts going to the auditory speech centre. A profound, sudden, destructive lesion such as it must have been, involving the auditory speech-centre, would necessarily entail at its commencement considerable disturbance in the motor vocal speech centre and in the visual speech centre. That these centres (motor vocal speech centre and visual speech centre) were not themselves directly implicated by the lesion is, I think, conclusively proved by the rapid recovery in the power of motor vocal speech and the very marked recovery in the power of reading which were established. When the patient came under my notice the word-deafness was still very complete; but with the exception of some degree of paraphasia the patient could express herself quite well in spoken speech, the only defect being that she occasionally made use of a wrong word and forgot names of objects (slight paraphasia). She could read aloud anything which was placed before her. She could understand short, written sentences which she could not understand when spoken (by the ear). She could express herself in writing, though not without mistakes. The inability to understand complicated sentences and the mistakes in writing which her letters show that she made can be quite well accounted for by the lesion in the auditory speech centre; they do not necessitate a lesion in the visual speech centre. The patient could repeat correctly words and sentences which she did not understand when spoken, and could write from dictation long sentences which she was quite unable to understand by the ear. It is very difficult to explain the fact that the ability to repeat spoken speech (heard by the ear) was retained, considering that the word-deafness was so marked. The most likely supposition seems to be that the repeated (mere echo) speech passed through the right auditory speech centre (instead of through the left auditory speech centre, the usual channel) to Broca's centre in the left hemisphere. Another point of great interest in the case is that for three or four days after the seizure (although the sensorium seems to have been clear) the patient was stone deaf. Absolute deafness is very rarely indeed, as Dr. Hughlings Jackson has pointed out, the result of a cortical lesion. The fact that this patient was stone deaf is suggestive of a bilateral lesion involving both auditory centres, or the fibres passing to both auditory centres. The supposition that the lesion was bilateral (involved both auditory

Hosted by Google

centres) is perhaps supported by the history of numbness and loss of power in the left hand which ushered in the attack. The patient, it must be remembered, was right-handed, and the chief lesion was almost certainly, therefore, situated in the left auditory speech centre. In the absence of a post-mortem examination it is useless to theorise further on the point. But, so far as I know, it has never been shown that a unilateral lesion involving only *one* centre for hearing in the cerebral cortex can or does produce stone deafness. When the patient came under my notice the power of hearing ordinary sounds was perfectly regained, but the power of understanding spoken language was still very imperfect. The remark which the patient herself volunteered ("Is it not a strange thing that I can hear the clock ticking and cannot hear you speak? Now let me think what that means") is a most striking one and emphasises this difference in a very marked way. After the attack and throughout the whole of the subsequent course of the case the patient's musical power seemed to be completely lost; she could neither sing nor play and did not appear to appreciate music of any kind. The notes of the case are as follows. The patient, a woman, aged twenty-six years, was sent to me by Dr. —— on Feb. 10th, 18—, with the following statement as to her previous history:—"The patient was confined on Nov. 22nd. On the eleventh day after delivery she complained of numbness in the left arm, and the nurse noticed that she had difficulty in lifting things with the left hand. This passed off in the course of the same day. On the afternoon of the following day the nurse, who had spoken to her and found her quite well a few minutes previously, was attracted by the sound of her breathing, and on approaching the bed found her in a drowsy condition and unable to speak. When I entered shortly after I found her in a lethargic state, breathing rather heavily, and apparently unable to speak or answer questions. Her eyelids were open, but she took no notice of what was going on around her. On the following day she was found in the same condition, except that she was not so drowsy; she had occasionally followed the movements of those in the room with her eyes. She took no notice when anyone spoke to her. If a question in writing was placed before her she would stare at it for a moment, but gave no indication that she understood it. The loudest noises did not attract her attention. She moved all her limbs freely and took liquid nourishment from a drinking cup when it was given to her. On the third day of her illness she was heard to mention the name of one of her children when he was brought into the room; and for the next three or four days she spoke a word now and again, and afterwards gradually went on to say short sentences more or less correctly. About the third day of the attack she showed that she heard noises, such as the shutting of the door, &c., and also that she understood to some extent *written* questions. She would reply to such a question in writing with considerable intelligence, writing in a good hand but with occasional misuse and mixing up of words. She could also read aloud from a book, with a mistake now and again in pronunciation. It was about four or five weeks after the beginning of her illness before she was able to understand any spoken word. At first she would only pick up very occasionally a single word in the conversation that was addressed to her and would repeat it to herself, but a slow improvement had gone on, and for the past four or five weeks she had been able to repeat with more or less correctness the words of a sentence spoken slowly by another, and to take up its meaning when finished. The pulse and temperature have been normal throughout. The following are copies of two letters which she sent to me; the first was written of her own accord and was a request for a tonic; the second she was asked to send so that I might judge whether there had been any improvement":—

"3rd January, 18——.

"DEAR DR. ——,—I think a little note to let you see and to think it is a little better yesterday. I two notes and ther is a little nonsense read yes I let me to let you know I would like to a deal to make stronger than I was, so I would like now to take more of the housekeeping and take care of the little children so I think you give me if from you so as to make me eating more for I be glad to so a great deal. May I get a little iron do you think? May I get from you just a little to make me something to sleep I allsay seem to think all take me all I am wrong. It reminds thinking all and I dont sleep and then I find the head so stupid too full, and I cannot too many. I am so glad you thinking well. I think you have been *very* kind to me and I am such a kind Doctor. I hope you to glad from us and give you a very Happy New Year and give you from —— and I a very kind regards.

"——."

This letter was written in pencil in a good hand; the letters were well formed; the punctuation, spelling, &c., were exactly as above.

The following, which was written in ink, shows decided improvement in the power of spontaneous writing:—

"January 24, 18——.

"DEAR DR. ——,—I am so glad to think now that you thought that I am improving quickly. How splendid it will be, when I hear you quite well, however I thought perhaps I would never know so much better. Every one has been very kind to us all. ..... How very very many every day you see to the ill ones. How fearfully sad it be must for you and how many getting better too. How *very* good and kind you have been to me. With very kind regards and —— join.

"——."

The previous history, as ascertained from her husband, was practically the same as that given above. He stated: "For the first three or four days after the cerebral attack she was stone deaf, unable to hear loud noises, such as the dinner bell rung loudly in her room. The first sound which she appeared to hear was a poker falling. She did not understand any single word which was said to her for four or five weeks. During this period she could speak and frequently asked questions, and she could understand short written questions and would answer them quite correctly. When she asked a question she would request that the answer should be made in writing. This was the only way in which she could be made to understand. During this period she was able to write, but in writing she made frequent mistakes. Before this confinement she was in perfect health. She has two other children. Both the previous labours were rapidly and satisfactorily recovered from. She is naturally of a nervous temperament and is at times very much depressed, thinking she will never recover her power of hearing and understanding spoken language. Since she began to regain the power of understanding spoken language I have noticed that when she is nervous or excited or fatigued her ability to understand what is said to her almost entirely disappears. When she fails to understand a spoken question she will often say so, and then ask that it should be written down. She then generally understands it." When I saw her the patient had a distinctly vacant expression. Her general health was now fairly good. She slept well. The appetite was rather poor, the tongue somewhat furred, and the bowels constipated. The heart was healthy. The radial pulse was 90 The temperature was normal. The kidneys and liver appeared to be healthy. She had had a good deal of neuralgic pain about the head. The teeth were bad; they had not been abstracted, for in the weak state in which the patient had been it had not been considered advisable to allow her to have chloroform. There was no paralysis in the face, arms, or legs. The grasping power of the right hand, as measured by the dynamometer, was twenty-five and that of the left fifteen (fairly normal for a woman of her physique who has passed through a long and severe illness). The patient was right-handed. The tactile sensibility in all parts of the body appeared to be normal and equal on the two sides. The knee-jerks were normal. The condition of hearing and of the auditory speech centre, so far as ordinary sounds were concerned, seemed quite perfect. She could hear a watch ticking and the tuning fork at a distance of two or three feet from either ear. At this stage of the examination she volunteered the statement, "Is it not a strange thing that I can hear the clock ticking and cannot hear you speak? Now let me think what that means." A marked condition of word-deafness was present. As has been stated above, she was completely word-deaf for several weeks after the onset of the attack. It was only during the past fortnight that she had answered any questions which had been put to her in spoken language. She could now understand some things which were said to her. She understood best when one word was said to her at a time. She was quite unable to understand a long or complicated question. She could understand some short sentences when the words were very slowly and distinctly spoken. It was often necessary to repeat a word more than once before she grasped its meaning. Often, too, she could only understand the significance of a question when the question had been repeated in a different form—a word of the same significance substituted for one which she could not understand. Thus, when asked very slowly and distinctly, "How old are you?" she answered correctly, after an interval, "Twenty-six." Asked, "When was your baby born?" she answered correctly after an interval, "On November 22nd." She always hesitated a long time and seemed to take much time to think.

Hosted by Google

out the meaning of simple questions before she answered them When asked, "Let me see your tongue," she made no response, and evidently failed to understand the question. Her husband said that she understood spoken language better when she did not see the speaker—when she was spoken to from a distance and when spoken to quietly and not loudly. He further said that she was able to understand children better than grown-up persons. She herself volunteered the statement to him that they (grown-up people) had too many teeth. Her power of understanding spoken language depended, he said, upon her spirits; it was always worse at night and when she was tired. When asked a question she often echoed the last part of it and then, after repeating some of the words, seemed to understand their meaning (the question here arises whether she did not get information as to the meaning of the words by aid of the ingoing—kinæsthetic—impressions which result from the vocalisation and motor movements attending the production of the words). Thus when asked, "Are you better?" she repeated the word "better," obviously in an automatic, reflex way, then brightened up and said intelligently, "Yes, better." Asked, "Have you any headache?" she repeated the word "headache" in an automatic way, then brightened up and said after hesitation, "Yes, often." Asked, "Are you giddy?" she echoed the word "giddy," then brightened up and said, "No." I subsequently ascertained that after the attack and throughout the whole subsequent course of the case the patient's musical power seemed completely gone; she could neither sing nor play and did not appear to appreciate music of any kind. With regard to the condition of the motor vocal speech centre, a certain degree of paraphasia was present; but with this exception the motor (emissive) faculty seemed to be little affected. She certainly spoke much more correctly (made use of spoken language much more correctly) than I would have supposed from the mistakes which she made in writing (see the letter of Jan. 24th, written a fortnight before I examined her). She volunteered statements, spoke spontaneously, asked questions, and expected to be answered; if she did not understand the answer she asked that it might be repeated, or asked that it should be written down. She seemed to be able to say almost everything she wished to say, but she occasionally made use of a wrong word; for example, she said "My hair" instead of "My skin." Her husband stated that during the early stage of the attack she made frequent mistakes of this kind, and she used to use the word "scarf" for almost everything. He added that the mistakes were chiefly confined to the names of things (objects); very soon after she regained the power of speech she could use the parts of language other than nouns quite well without making mistakes. (In her written speech the mistakes involve all parts of speech, nouns perhaps least of all.) Often when she could not get a word she used to spell it and then pronounce it. In the act of spelling the auditory speech centre and the visual speech centre are both brought into play. Most people spell chiefly by the revival of auditory impressions, though the influence of the visual speech centre is in many persons very active; witness the fact that when doubtful about the spelling of a word many people write it down to see how it looks. In most people both sensory speech centres are called into use. The patient in Case 2, though unable to read, could write quite well, but could not read a single word that she had just written, yet she could spell perfectly. This patient, who was almost completely word-deaf, often when she could not get at the meaning of a word, would spell it out, then pronounce it, and then understand it. As to the ability to repeat spoken language, although she was unable to understand most things that were said to her, she could repeat words and sentences which she did not understand. This was very remarkable and difficult to understand. Further—and this was also very curious—she could write down words and sentences which she did not understand (when spoken), and could then understand them after she had written them. I asked her, for example, the question, "Do you like to come to Edinburgh?" She did not understand it. I then asked her to repeat it after me. She did so without hesitation. I then asked her to write down the words she had just said. She did so without the words having to be repeated a second time, and she then undoubtedly understood the question. At this stage of the examination her husband volunteered the statements that her memory was excellent and that "she repeated what she heard by sound and not by sense." When asked, for example, "How old are you?" she repeated, "Old are you"; then brightened up, and after an interval said "Twenty-six." When asked, "Have you any headache?" she repeated "Headache"; then brightened up and answered, "Yes, every day," and pointed to her forehead. She repeated after me, "Monday, 22nd," "Where are you?" "Where are you to-day?" and "Are you in Edinburgh?" As to the condition of vision and the visual word centre, her sight was perfect, V. = $\frac{20}{20}$. There was no hemianopsia. The optic discs were normal. The pupils were equal and of medium size. She readily understood short questions which were put to her in writing. She occupied a good deal of her time in reading, but her husband said that she did not seem to understand much that she read; she apparently was unable to grasp the meaning of long and complicated sentences, though she generally had no difficulty in understanding short written questions. She seemed, he said, only to be able to understand one sentence at a time. If she read for any length of time she seemed to get confused and not to be able to understand. She recognised and generally named correctly any object which was shown to her. Thus she named correctly a watch. Asked what a tuning fork was, she said "for music, a fork to sing" (slight degree of paraphasia), made it vibrate and held it to her ear, showing that she understood what it was. When asked to pick out a knife, pencil, and buttonhook from a number of different objects she did so correctly. She named scissors, pencil, and india-rubber correctly. The following questions, which she was unable to understand by the ear (when spoken), she was able to understand when written:—"Can you repeat words after me?" "Say the words 'I say.'" "Do you like to come to Edinburgh?" "Can you write what you have just said?" "What do you call it?" (showing her a watch). "Please shut your eyes and tell me what you hear." "Squeeze it [dynamometer] as hard as you can." "Do you feel quite well when you are touched?" "Please look steadily at my eyes and tell me if you see my finger moving." "Do you see my finger?" "You see my finger quite distinctly in all positions?" She read aloud without any hesitation, correctly, but with a somewhat monotonous expression, the following sentence from a book on my consulting-room table: "No issue of a medical journal would be complete at the present time without containing the latest development in this greatest medical experiment of all time." Her mental faculties seemed to be comparatively little impaired. Her husband said that her memory was very good. She could multiply, add, and subtract figures correctly, but she performed all these mental operations very slowly. The following are illustrations. When asked to multiply 60 by 3, the answer, after hesitation, was written by the patient 180. When asked to subtract 54 from 162 the answer was written by the patient slowly, 108. When asked to add together 122 and 101, the answer written by the patient was 223. The sense of smell seemed unimpaired. When asked, "Can you smell?" she made no indication that she understood the question. Some oil of peppermint was then placed to her nose. She immediately said, "Yes, something like strong sweeties." When asked, "Is it peppermint?" she said, "Yes—taste said to be good." The future progress of the case is told by the following letters:—

"March 9th.

"I think it is about a month since we went to Edinburgh to see you. My husband thinks I can hear a very little better, and I am so glad and thankful and it will be splendid when to be quite better. I have taken two bottles from you have given. I have got very bad with indigestion and with newlargia in the system. I got from Dr. —— antipyrine powders. We think of going to —— and I hope the change will be good for me and will be glad if I feel stronger."

I append a portion of this letter in facsimile to show the exact character of the writing (see Fig. 21).

"April 9th.

"Many thanks for your last note. We went to near —— for a week, but the weather was very very cold.

"We think I can hear a little better, but the progress seems very slowly and very little of the general conversation.

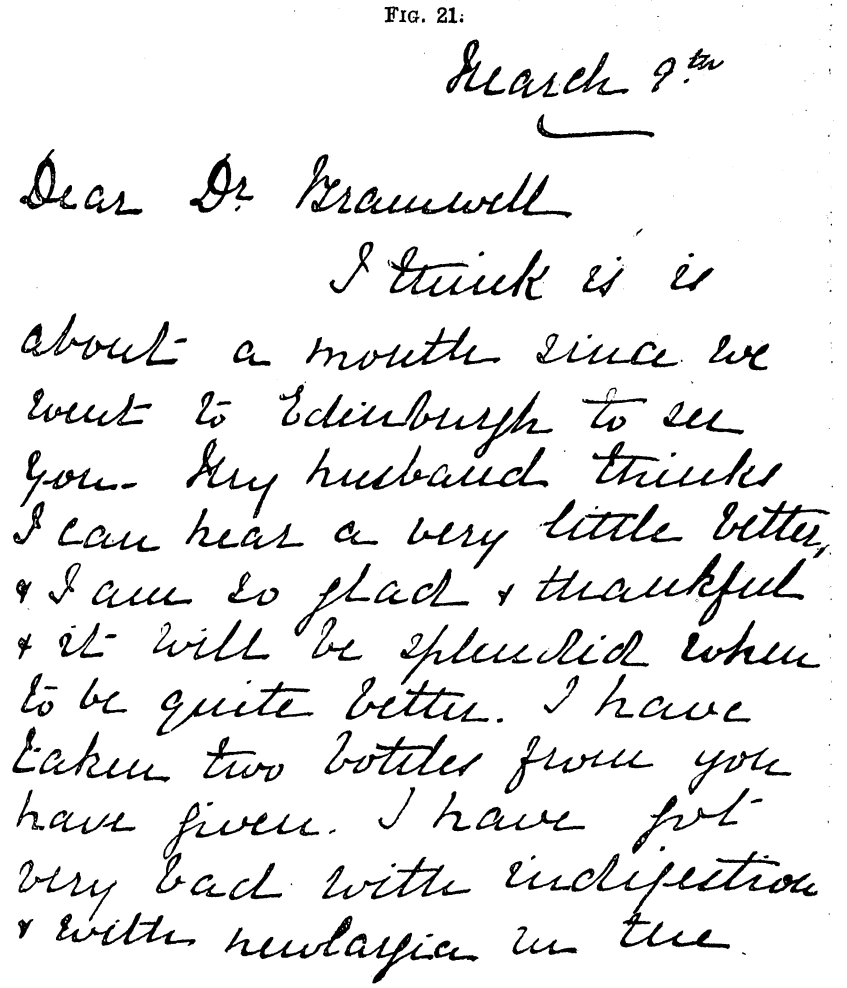
"I have got still indigestion and so very cold and chilly all through I think from the circulation of the blood.

"The worst of all the pain is newlargia in my head and I have no toothache. Do you think there is two kinds of headaches, newlragia and from the forehead so hot and always aching, sometime I think from not enough of blood or too slow, or weakness, and such a horrid feeling of lightness and dazed. I will be so glad when I feel I am better. Sometimes I wonder if I really will be so well as before the illness."

On May 28th her medical attendant wrote to me as follows:—

"Mrs. —— (case of aphasia) has not been so well for the past month. After you saw her in February she slowly but steadily improved in the matter of understanding spoken speech, and about six weeks ago if one

Hosted by Google



spoke slowly and distinctly she took in almost everything that was said to her. She could not, however, take part in a general conversation, but occasionally picked up what was being said by those around her. Her power of expressing herself in writing, as you would observe from the letters she wrote, had also improved very much. All along she has complained a good deal of uneasy sensations and pain in her head. She has also had a considerable disinclination for food and there has been much difficulty in getting her to take an adequate amount of nourishment. About a month ago she commenced to complain of feeling very tired and weak, and also of some pain in the head—across the eyebrows and over the vertex. She took to bed and has not been up since. The pain seemed to be constant, with paroxysms of increased severity, and accompanied by great intolerance of light and sound. There was no paralysis. Sometimes she complained of pain in the left arm and leg, and once or twice of stiffness of her left forearm. The pulse was slightly quickened, from 96 to 100, but regular; the temperature was normal; the tongue was coated and she had a great dislike for food. Examination of the eyes, so far as it could be made, revealed nothing abnormal. About ten days ago she ceased to complain of the pain in her head, but at the same time began to show a great falling off mentally. She has much less power of expressing herself and does not understand what is said to her so well. She is very emotional. Occasionally she rambles a good deal—imagines there are people in the room, that she is not in her own house, &c. She is rather thin, but her general strength is fairly good. The treatment she has got lately has been ice to the head when the pain was bad, blister to the nape of the neck, small doses of iodide of potassium combined with bromide of potash, and frequent feeding. If you have any suggestions to make I will be very glad to hear from you."

And again on Aug. 6th :—

"I have omitted to let you know of the death of our patient, which occurred about five weeks ago. After I wrote you she got steadily weaker. She fell off very much mentally—talked incoherently, understood very little of what was said to her, and had the delusion that she was not in her own house, that there were people in the room, &c. About a week before her death the temperature began to rise at night and ranged from 101° to 103° F., and on the day she died it was as high as 108°. I tried hard to get a post-mortem examination, but failed."

(To be continued.)

FIG. 21.

March 9th

Dear Dr Bramwell

I think it is about a month since we went to Edinburgh to see you. My husband thinks I can hear a very little better, & I am so glad & thankful & it will be splendid when to be quite better. I have taken two bottles from you have given. I have got very bad with indigestion & with neuralgia in the

Portion of a letter written by the patient on March 9th (Facsimile).

THE MALIGNANT TUMOURS OF INFANCY, CHILDHOOD, AND YOUTH.

BY W. ROGER WILLIAMS, F.R.C.S. ENG.,
FORMERLY SURGEON TO THE WESTERN GENERAL DISPENSARY; AND SURGICAL REGISTRAR, MIDDLESEX HOSPITAL.

(Continued from p. 1196.)

TESTIS.

THE malignant neoplasms of the testis, especially those of early life, are remarkable for the great frequency with which heterotopic structures—such as cartilage, striped muscle, unstriped muscle, and epithelial elements, often ciliated—are found in them. Many circumstances point to aberrant elements connected with "rests" of the Wolffian body, lodged in the rete testis, as the germs whence most tumours of this kind arise. It is believed that the junction between the Wolffian tubules and the tubuli seminiferi is brought about by the forward growth of the Wolffian tubules into the hilum. At this stage fragments of the adjacent proto-vertebral matrix, &c., may readily be dislocated and become embedded in the evolving organ, where they constitute the "rests" above mentioned. The difference between the ovarian and testicular development in this respect may be the reason why these heterotopic elements are absent from ovarian neoplasms; at any rate, the ovaries are developed in just as close proximity to the proto-vertebral matrix as the testes, and were there not some special difference in their ontogeny the former would be just as liable to these heterotopic inclusions as the latter. Of 51 malignant testicular neoplasms tabulated by Curling,[66] in 5 the disease began under the age of five years and in 1 between fifteen and twenty years. These tumours are occasionally met with at birth and sometimes they are bilateral. They are often described as "cancers," but in reality they are almost always sarcomata, and this is shown by the nature of their metastases. Examples have been met with by Parker[67] at three months, Hutchinson[68] at five months, Silcock[69] at eight months, Depaul[70] at ten months, Chaffey[71] at eleven months, Louvet[72] at sixteen months, Schlegtendal[73] at eighteen months, Butlin,[74] Marsh,[75] and Hertzberg[76] at two years, Johnson[77] at two and a half years, Battle[78] and Neumann[79] at three and a half years, Jacubasch[80] at six years, and Ribbert[81] at thirteen and fourteen years. Trólat[82] has collected 26 cases recorded prior to 1884. In a congenital case of this kind seen by Weber,[83] in which cartilage largely predominated, the tumour—which at birth was of the size of a pigeon's egg—increased in the course of fifteen months to the size of a goose's egg. I have seen a case of adeno-myxo-sarcoma of the left testis in a youth nineteen and a half years old, who died from acute dissemination of the disease sixteen days after castration; when metastatic nodules were found in skin, eye, triceps muscle, both lungs, liver, both kidneys, small and large intestine, and in the retro-peritoneal glands. Edwards[84] has met with sarcoma of the

Hosted by Google

epididymis in a child four years old, and Walsham[85] with myxo-sarcoma of the spermatic cord in children aged thirteen months and four years. Marchand thinks that some malignant tumours of the epididymis arise from aberrant suprarenal "rests."

EYE.

In infants no part of the body so frequently originates malignant neoplasms as the eye. Nearly all tumours of this kind are gliomata, but sarcomata of the uveal tract, both pigmented and non-pigmented, are now and then met with. Of 155 consecutive malignant intra-ocular neoplasms from the Prague Clinic 24 occurred in children of from one to ten years old. Gliomata are peculiar to early infancy; they are rare after five years of age, and they hardly ever occur after twelve years. Gliomata have been met with at birth, and exceptionally both eyes are simultaneously affected, but it is much commoner for the disease to begin in one eye and thence to spread to the other. Of 8 cases within my own experience the ages at which symptoms of the disease first appeared were seven months, nine and a half months, fourteen and a half months, sixteen months, one and three-quarter years, two years, three years, and eleven years. In the first 4 of these cases the disease was almost certainly congenital. In 1 case metastases were met with. There are good reasons for believing, as Wintersteiner[86] has shown, that most tumours of this kind arise from "rests" sequestrated from the evolving retina during embryonic life. An instance of congenital sarcoma of the choroid has been reported by McKay,[87] and Williamson[88] has met with spindle-celled leuco-sarcoma of the iris in a girl fourteen years old.

Besides such tumours as the foregoing, a certain number of malignant neoplasms arise in the orbit during early life, quite independently of the eyeball. Thus Courant[89] removed a large congenital teratoid tumour from a newly-born male child, which contained numerous heterotopic elements, and there was defective development of the corresponding orbit. It seems likely that tumours of this kind may originate in association with fœtal inclusions connected with the orbito-frontal fissure.

Probably the "ossifying epithelioma" of the orbit described by Silcock[90] in a young boy, as well as the various more or less malignant ossifying and chondrifying orbital tumours, such as those recorded by Reid[91] in a youth aged nineteen years and by Beaumont[92] in a girl aged sixteen years, also originate from embryonic inclusions. At any rate, we know that such inclusions not infrequently do arise in this vicinity, of which the various congenital orbital cysts and other developmental defects are the evidence. Moreover, Axenfeld has demonstrated the frequent occurrence of islets of cartilage in the otherwise normal orbit. The following instance has come under my own observation.

CASE 5.—A young woman, aged nineteen years, with left proptosis and other signs of orbital tumour. On examination a firm nodulated new growth was felt attached to the upper margin of the orbit. The adjacent lymph glands were normal. Excision of the tumour was performed, and the growth seemed to be limited to the upper part of the orbit and was unconnected with the eye. Recurrence *in situ* took place two and a half years later and excision was again resorted to. A further recurrence took place nine months later, for which the orbit was cleared out. The globe and optic nerve were quite free from disease. The tumour seemed to have originated from the upper and outer part of the orbit.

Other examples of rapidly growing sarcomata of the orbit have been demonstrated by Knaggs[93] in a child aged two and three-quarter years; by Lambert[94] in a boy, aged three years; and by Snell[95] in a girl aged four years, &c. Lagrange[96] has met with a myxo-sarcoma of the sheath of the optic nerve in a boy aged five years.

Besides the foregoing, other sarcomata are found in the orbit which originate quite outside it. The following instance in which the disease arose from the region of the basi-sphenoid has come under my notice.

CASE 6. — A healthy-looking youth, aged eighteen and a half years, with left proptosis and other signs of intra-orbital tumour. The scar of a former operation was seen along the left side of the nose. A swelling from a recurrent growth was present in this region. The left naris was blocked by the new growth. The disease was of eighteen months' duration. Six months previously a sarcomatous growth was removed from the left naso-orbital region by incision along the side of the nose. It seemed to spring from the basi-sphenoid. The floor of the orbit was perforated by the tumour. Soon afterwards recurrence set in. No further operation could be done.

Some remarkable examples of neoplasms of this kind have been published. Lawson[97] had under his care an interesting case of this kind.

CASE 7.—The patient was a male child only two days old, in whom the disease existed at birth; there was rapid recurrence after removal of the tumour, which was a multilocular cyst with much solid new growth. On histological examination it proved to be a round and spindle-celled sarcomatous teratoid new formation containing cartilage, epithelial elements, and other heterotopic structures.

Holmes[98] has met with a similar case. Other instances have been recorded by Targett[99] in a male infant aged one year; by N. Moore[100] in a boy aged one and a half years; by Chaffey[101] in a female aged three years; by Jessett[102] in a female aged one year and seven months; by Pollock[103] in a female five years old; and by Dickinson[104] in a boy aged twelve years. Such tumours probably arise in connexion with developmental aberrations in the vicinity of the anterior extremity of the notochord.

Several instances of cancer of the conjunctiva in youth are on record. Rogman[105] has recently reported an instance in a boy aged fourteen years, and Panas has seen similar cases at twelve and thirteen years of age. The latter observer has pointed out the remarkable fact that in nearly all these cases the disease begins at the outer side of the lower part of the corneo-scleral margin, which is just the spot where congenital dermoid patches are of commonest occurrence.

KIDNEY.

Next to the eye the kidney is the locality in infants whence malignant neoplasms most frequently arise. Judging by the large number of recorded cases, malignant disease of the kidney is of even more frequent occurrence than Duzan's list would lead us to suppose; and some writers consider that the kidney is more often affected than the eye. This proclivity of infants to malignant renal disease is the more remarkable when the extreme rarity of the affection at other periods of life is borne in mind. Tumours of this kind are invariably sarcomatous, although in the older reports they are often described as "cancers," owing to the occasional presence of epithelial structures of simple tubular or papillary cystic type, in the sarcomatous matrix. In certain cases these epithelial elements may be derived from "rests" of the Wolffian body, or from separated fragments of the renal parenchyma itself.* Striped muscle fibres are frequently met with; and it has been remarked that when they are most abundant the tubular structures are generally absent or scanty. I am not aware that either cartilage or bone has been found in these neoplasms, but angiomatous structures are of common occurrence. It seems probable, from recent observations by Lubarsch,[106] McWeeney,[107] and others, that renal sarcomata may not improbably often be derived from suprarenal "rests." Sudeck thinks that some of them arise from "rests" of hepatic origin. The subject is still *sub judice*. The development of the kidney is of such a complicated nature, and so many adjacent structures are liable to be implicated, that it would be surprising if fragments of some of them were not frequently included in it. To such sources we must look for the germs whence most of these neoplasms arise. Renal sarcomata are frequently bilateral, multiple *ab initio* and congenital, but most cases are first noticed during early infancy. Like their congeners of the testis and ovary, these tumours are generally circumscribed, and they usually indent the contiguous renal tissue rather than infiltrate it. Cohnheim[108] seems to have based his celebrated theory of neoplastic pathogeny largely on a case of this kind which he observed in an infant aged sixteen months. In the left lumbar region he found a large tumour, to the border of which the remains of the left kidney, otherwise unaltered, adhered. Within the capsule of the right kidney, at its upper end, there was also a small round circumscribed tumour quite distinct from the kidney substance. Both contained striped muscle fibres and sarcomatous tissue. Of 37 examples of these tumours collected by Röhrer[109] in children aged under ten years, 16 were under two and 31 under five years, and 1 was newly born. Leibert[110] has since tabulated 50 similar cases, and Jacobi[111] 43. Paul,[112] Windle,[113] Eve,[114] and others have published interesting papers on this subject.

I have seen a case of malignant disease connected with the kidney of a male child aged two years quite different from any of the foregoing. Laparotomy was performed for a large tumour occupying the left renal region, but the adjoining glands were so extensively infiltrated that its removal was not attempted. The child died not long afterwards,

* The number of lobules composing the human kidney is greater than is generally believed. According to Maresch, from eight to eighteen distinct lobules can easily be recognised in the fœtal organ. Many incomplete lobules also exist, so that altogether traces of from twenty to fifty lobules may be found in every fœtal kidney.

Hosted by Google

and at the necropsy the left kidney was found to be surrounded by a mass of soft, ecchymosed myxo-sarcomatous new growth, which had evidently sprung from the peri-renal fatty envelope, for it was distinctly outside the renal capsule, and the kidney itself was unaffected I have since seen a similar case in an adult, and the glands being unaffected it was successfully removed.

Cancer of the kidney occurs only in adults, and it is very rare; instances have been recorded at the age of twenty-one years by Israel,[115] by N. Moore[116] in a man aged twenty-five years, by Sharkey[117] in a woman aged twenty-eight years, and by Newman[118] at various ages.

SUPRARENAL BODY.

Although the suprarenals so rarely originate malignant neoplasms, that of 8378 consecutive cases tabulated by me only 1 arose in this connexion; yet of the 36 cases of which I have records I find that more than one-third belong to the periods of infancy and childhood. These tumours are occasionally met with at birth, and they may be bilateral. They are invariably sarcomatous, although often described as cancerous. Accessory suprarenal bodies sometimes originate similar tumours, but it is probable that some neoplasms thus described spring from aberrant renal lobules. In a child eight and a half years old Ribbert[119] met with a tumour of this kind which was connected with the outside of the capsule of the kidney in the vicinity of the renal pelvis. Marchand has found accessory adrenals in situations far removed from their normal habitat, such as the margin of the broad ligament and the epididymis.† Instances of malignant suprarenal tumours have been reported by Parker[120] and Dalton[121] in infants only a few weeks old, by Martin[122] at five months, by Cohn[123] at nine months, by Eberth[124] at fifteen months, by Fox[125] and Mankiewicz[126] at two years, by Earle[127] at three years, by Lazarus[128] at four years, by Greenhow[129] at twelve years, by Peacock[130] and by Fränkel[131] at eighteen years.

BLADDER.

In this organ sarcomatous tumours are occasionally met with in early life. The disease usually assumes the polypoid form, and multiple tumours are often met with, or a polypoid condition of the mucosa accompanies the sarcomatous tumour. The condition is analogous to that which so frequently occurs in the vagina; and no doubt its origin is connected with similar embryonic developmental aberrations. These growths are commonest in the lower part of the bladder—that is to say, in the region most intimately connected, developmentally, with the vagina. Steinmetz[132] has collected 32 cases of this kind. Most instances are met with in early infancy, and both sexes are affected. Cases have been reported by D'Arcy Power[133] in an infant, by Shattock[134] at one and a half years, by Dittrich[135] at one and three-quarter years, by Chaffey[136] at three years, by Löhr[137] at three and three-quarter years, by Chiari[138] at five years, and by Fenwick[139] at eight years.

PROSTATE.

Of 96 primary malignant neoplasms of the prostate tabulated by Engelback, 10 per cent. originated in early life—3 in the first year, and 6 in the next 9 years—all of these early neoplasms being sarcomata. Of 16 recently recorded cases collected by me, in 2 the malady began under twenty years of age. It is a very rare affection at any time of life. The instances met with in early life are invariably sarcomatous; and, according to Barth, about half the recorded cases of prostatic sarcoma belong to this period. Examples have been reported by Jordens[140] and Barth[141] at nine months, by Solly[142] at three years, by Wind[143] at five and a half years and at eight months, by Barth[144] at seventeen years, by Coupland[145] at nineteen years, and by Wyss[146] at various ages.

LIPS, TONGUE, AND ŒSOPHAGUS.

The following examples of "cancer" of the lip in early life have lately been recorded by Krasnobaeff[147] (of the upper lip and right ala nasi) in a child eight years old; by Batashoff[148] (of the lower lip) in a girl aged thirteen years; and by Gangolphe[149] (of the upper lip) in a boy aged fifteen years. In all the disease was of the epidermoidal variety. The foregoing cases were "histologically verified"; but whether, in doubtful cases, a diagnosis based solely upon histological analysis can be implicitly trusted is a question I should be inclined to answer in the negative. For the present, therefore, it will be best to regard the morphological diagnosis of such cases as the foregoing as still *in limine*. Of 1003 cases of cancer of the lower lip collected by Paget and Jessett[150] from various sources there was not a single instance of the onset of the disease under twenty years of age; of 43 consecutive cases under my own observation the earliest age at which the disease was first noticed was twenty-six years; Winiwarter, however, reports having met with one instance of lip cancer under twenty years.

In the tongue a few examples of cancer and sarcoma in early life have been met with. In Variot's[151] case of "epithelioma" of the tip of the tongue, in a boy only eleven years old, the diagnosis of cancer rested solely upon the histological examination, the clinical signs of cancer being absent. Billroth[152] has met with the disease in a youth aged eighteen years, Winiwarter[153] at twenty years, and Haward[154] in a woman aged twenty-three years. Of 122 consecutive cases in males under my observation the youngest was twenty-five years and seven months old; of 15 cases in females the youngest was thirty-four years. Of 290 cases tabulated by Barker[155] the youngest was twenty-six years. Of Gross's 133 cases the youngest was twenty-nine years, and of Winiwarter's 136 cases the youngest was twenty years. Thus of these 696 cases in not a single instance did the disease begin under twenty years. About 24 cases of sarcoma of the tongue have been recorded, and several of these originated in early life. Congenital cases of this kind have been reported by Jacobi[156] and Mason;[157] by Stern[158] at four years, and by Lang[159] at twelve years. Such tumours are often multiple *ab initio*, and in the last-named case the neoplasm contained cartilaginous, osseous, and fatty structures. Godlee[160] has met with an adeno-sarcoma of the tongue containing a calcifying nodule in its centre in a woman aged twenty-four years. A congenital form of "epulis" has been lately described by Olivier,[161] who believes it arose from "rests" of the gingival mucosa; of this Gore[162] also has reported a good example. Similar cases had previously been described by Malassez. Myxo-sarcomatous naso-pharyngeal polypoid tumours are not infrequently met with in early life growing from the top of the pharynx. Cases have been reported by Lloyd[163] in a youth aged seventeen years and by Wolfenden[164] in a girl aged fifteen years. I have seen similar instances in a youth, who first noticed the disease when only twelve years old, and in a girl (adeno-sarcoma) aged nineteen years. Berg[165] has reported an instance of malignant disease of the soft palate in an infant aged four and a half years. Bryant[166] met with "cancer" of the tonsil at seventeen years, and Castex[167] with lympho-sarcoma in a girl aged seven years. In a young woman aged twenty-one years S. Paget[168] has seen a sarcomatous tumour of the hard palate with which epithelial pearls were associated. Cancer of the œsophagus is very rarely met with under thirty years of age. Of 18 cases under my own observation the earliest age at onset was thirty-two years and eight months. Stephan[169] has reported a case of œsophageal sarcoma in a child five years old.

STOMACH.

In early life malignant disease of any part of the gastro-intestinal tract is of the greatest rarity. Some idea of the extreme infrequency of cancer of the stomach at this period may be gathered from the fact that of 2075 cases tabulated by Welch only 2 originated under the age of twenty years. Of 2000 necropsies on children analysed by Steiner and Neureutter not a single instance of malignant disease of the stomach was met with. Nevertheless, several instances of alleged cancer of the stomach in infancy have been recorded; and in at least two of them the disease was congenital. In Wilkinson's[170] case marked thickening and induration of the pylorus was noted in a newly-born child; but since none of the other clinical features of cancer were present, and no microscopical examination was made, it is much more likely that the morbid condition was congenital hypertrophy rather than cancer. Several instances of this form of hypertrophy in infants have been met with (Finkelstein, Grau, Kops, and others), and an example of it has lately been recorded by Pitt[171] in an infant seven weeks old. A remarkable case is Cullingworth's,[172] in which a polypoid tumour—evidently congenital—was found growing from the lower border of the pylorus in an infant five weeks old. Histological examination revealed tubular structures lined

† According to Pettit the suprarenals are ontogenetically allied with the sexual glands, being derivatives of the germinal epithelium.

Hosted by Google

by cylindrical epithelium, as in cancer; but in the absence of any of the clinical signs of malignancy I should think it much more likely that the disease really was congenital adenoma, with which the histological appearances were certainly consistent. In a case of so-called cancer of the stomach in an infant one and a half years old, reported by Kaulich,[173] the disease was probably sarcomatous, but as other organs were affected it is doubtful whether the disease really originated in the stomach. In Kühn's[171] case of "Adenoid Cylinder-celled Cancer" in a female infant two years old the disease was probably adeno-sarcoma of congenital origin. N. Moore[175] has described a case of "Alveolar Cancer" of the cardiac end of the stomach, close to the œsophagus, in a girl aged thirteen years. The type of cancer met with in this case, as well as the situation of the tumour, are very unusual, and to my mind these circumstances suggest the origin of the disease from congenitally dislocated œsophageal glandular structures. An instance of cancer of the pylorus (with dissemination in the spleen) in a child aged fourteen years has been published by Scheffer,[176] at seventeen years of age by Köster[177] and Landouzy,[178] at nineteen years of age by Hirtz,[179] and at twenty years of age by Glynn[180] and others.

Sarcoma of the stomach is a very rare affection, of which a few examples have lately been met with. Of 352 consecutive cases of malignant disease of the stomach tabulated by me there was not a single instance of sarcoma, and Gurlt's table, which comprises 1103 similar cases, is equally devoid of sarcoma. Pitt[181] has described four cases of lymphadenoma of the stomach in boys aged from four to twelve years; and Hueter[182] reports examples of congenital adenoma.

INTESTINE.

More cases of malignant disease are met with in early life in the intestines than in the stomach. The instances of so-called cancer of the small intestine reported by Duncan[183] at three and a half years, and by Spanton[184] at twelve years (ileum), were evidently sarcomatous. Madelung[185] has described 14 cases of sarcoma of the small intestine in patients of various ages, mostly young; these growths are often multiple and sometimes congenital. In the large intestine similar neoplasms have been met with, but they are rarer. In an infant a few days old Stern[186] met with a fungoid sarcomatous tumour growing from the ileum which had caused death by obstruction. It was an endothelial angio-sarcoma, evidently of congenital origin. Spanton's case of "medullary cancer" of the ileum in a twelve-year-old child belongs to the same category, and with it Steiner's[187] case of "alveolar cancer" of the sigmoid in a child nine years old should be classed. Pépin[188] has described a case of sarcoma of the jejunum in a female child five years old; and Bessel-Hagen[189] a similar case in a boy aged seven years. Abbe[190] has met with sarcoma of the caput coli in a youth aged sixteen years; Homans[191] with sarcoma of the cæcum in a girl aged five years; Kanthack[192] with myxo-sarcoma of the colon in a lad aged seventeen years; and Debrunner with sarcoma of the transverse colon in a boy three years old. Of 227 intestinal cancers in which Gurlt noted the age distribution the disease originated under twenty years in 2—viz., at thirteen years and nineteen years.

(To be concluded.)

ON SENILE TUBERCULOSIS AND SUBCUTANEOUS (TUBERCULOUS) ULCERATION.[1]

BY HOWARD MARSH, F.R.C.S. ENG.,

SURGEON TO, AND LECTURER ON SURGERY AT, ST. BARTHOLOMEW'S HOSPITAL, AND CONSULTING SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

SEVERAL examples of tuberculous disease occurring in old people have, within the last few months, been under observation in the wards of which I have charge in St. Bartholomew's Hospital. I hope it may be of interest if I briefly relate some of them, and make some reference to the general question of senile tuberculosis. Some discussion appears to be desirable, for although Sir James Paget's original essay on senile scrofula was published in 1867, in some of the principal manuals of the present day the subject is not even mentioned, while in others it is referred to in so cursory a manner as to convey the impression that it is of little importance in the practice of surgery.

[1] A paper read before the Medical Society of London on April 26th, 1897.

My own experience has led me to believe that the opposite of this is, in reality, the case. The disease in its various manifestations is frequent rather than rare; its early recognition is often difficult; indeed, it is apt to be overlooked by those who regard it as a mere pathological curiosity. Prognosis is generally very unfavourable, and the treatment raises questions of considerable gravity from the patient's point of view. Among the cases met with have been the following:—

CASE 1. *Large double iliac abscess, probably dependent on Pott's disease.*—The patient, a man aged seventy years, was admitted into St. Bartholomew's Hospital about six weeks ago with two iliac abscesses of very large size; that on the left side was already pointing, and proved, when it was opened, to contain about two pints of pus. The cavity was scraped and drained. This abscess is now very nearly healed. The second abscess will be opened in a few days.

CASE 2.—A woman, aged seventy-four years, was recently admitted for an iliac abscess on the right side. Here, as in the former case, there was no angular curvature or other conclusive evidence as to the precise origin of the abscess; but it must be remembered that angular curvature may be absent, notwithstanding the presence of advanced Pott's disease in patients of middle or advanced life. In such patients the vertebræ are so massive and formed of such strong bone, that, although excavation occurs, their framework often resists deformity; while in other cases the disease takes the form of a spreading periostitis, and excavation is either absent or present to only a slight extent. It seemed probable that this patient and the patient in Case 1 were suffering from Pott's disease.

CASE 3.—Last year a woman, aged sixty-nine years, was admitted into the hospital suffering from spinal disease. On examination she was found to have a very marked angular curvature at the level of the eighth dorsal vertebra. The spinous process of this vertebra was sharply prominent and the column above this point for eight or nine inches was perfectly straight. The patient said that for the previous twelve months she had suffered from pain in her back and round the sides of her trunk, and that the deformity of the spine had been progressing for nine months. She could now move and walk only with difficulty, and was obliged to lie down during the greater part of the day. This patient, who came from a distance, was supplied with a poroplastic jacket and discharged, and I heard no more of her. That the angular deformity in this case was due to tuberculosis seemed clear. The alternative view that it depended upon new growth—sarcoma or carcinoma—appeared to be negatived by the absence of severe pain, and of paralysis, and also by the period over which the case had extended; for malignant disease of the spine is generally fatal within nine months, and this patient, although her spinal disease had existed for more than nine months, was still in very fair general health and condition.

CASE 4.—The following remarkable case has lately been under observation. A woman, aged seventy-two years, developed what was evidently tuberculous disease of her left ankle. The joint became the seat of a slowly increasing fusiform swelling involving it in all its aspects. The patient was unable to bear any weight upon the foot and the muscles of the calf underwent marked atrophy. In the course of three months suppuration occurred, and in spite of free incision, scraping, and drainage, pus burrowed widely amongst the tendon sheaths of the deep muscles. Amputation was performed at the junction of the middle with the lowermost third of the leg. The stump healed favourably, although very slowly. A year afterwards the lower third of the left ulna became the seat of extensive tuberculous periostitis, attended with dusky redness and œdema of the skin and considerable pain. Free incisions were made and the granulation tissue was scraped away. The wound slowly healed and the patient remained well for three years. At the end of this time her right ankle became involved in considerable swelling, which seemed obviously to depend upon tuberculous synovitis. Within two months the joint had become disorganised, and the ligaments had been so far destroyed that free lateral movement was easily produced. Suppuration occurred, and as the tissues in the lowermost third of the leg were becoming œdematous, amputation was performed six inches above the joint. The patient, who was now seventy-six years of age, bore the operation perfectly well and the wound soon healed. On dissection the joint was found to have undergone extensive tuberculous disease. The synovial membrane was converted into a thick layer of pulpy granulation tissue. The articular cartilage was almost destroyed, the bones in places were somewhat deeply eroded, and the principal ligaments had in great part disappeared. Microscopic examination showed that the disease was beyond question tuberculous in character.

CASE 5.—There was recently in the hospital a patient, aged seventy-two years, who had been suffering for fifteen months from tuberculous disease of the outer and front portion of the left foot. On examination, the metatarso-phalangeal joint of the little toe was found to be disorganised and occupied by granulation tissue, and a sinus led into the substance of the external cuneiform bone, which was in a state of rarefying osteitis.

CASE 6.—Two years ago a man, aged fifty-six years, was under treatment for what at first appeared to be osteo-arthritis of his right knee. The joint had recently become a little swollen, stiff, and painful. There was some grating on movement, and the muscles of the thigh were markedly wasted. The knee, however, became more and more swollen, the synovial membrane was thickened and pulpy, and the skin over the joint was dusky and abnormally warm. Within three weeks of the patient's admission, and about two months after the commencement of the disease, the joint suppurated, and in spite of complete rest, went from bad to worse, and was amputated three weeks later. On examination it was found extensively disorganised by tuberculous disease. The synovial membrane was converted into a thick layer of granulation tissue, the articular cartilages were eroded, and reduced to thin wafer-like plates, detached from the bones. The bones themselves were in some parts deeply ulcerated. The patient quickly recovered from the amputation.

Several other examples of senile tuberculosis which I remember to have seen might be related, but it will be enough merely to mention them. A patient, aged sixty-five years, with tuberculous epididymitis; a man aged sixty-eight years, with enlarged and suppurating cervical glands; a man aged seventy-five years, with rapid disorganisation of the wrist joint, requiring amputation; a woman aged sixty-seven years, with tuberculous caries of the metacarpal bone of the thumb; a woman, aged sixty-two years, with tuberculous disease of the axillary glands, imitating carcinoma; and tuberculous disease of the kidney in a woman aged fifty-eight years.

The symptoms produced by senile tuberculosis are identical with those met with in the more severe examples of the corresponding forms of tuberculous disease in the young—e.g., in tuberculous disease of the tarsus in a person aged seventy years, the character, position, and extent of the swelling, the congested and dusky condition of the skin and the appearance of any ulcers that form—all these are indistinguishable from the like features when they are observed in a patient aged ten years. The main difference—needless to say, it is one of great importance—between tuberculosis in the old and in the young is that while in the young, if adequate treatment is adopted early and properly carried out, recovery is the rule; in the old, in spite of the best known treatment, the progress of the affection is in the majority of cases from bad to worse. In a joint, for example, the synovial membrane rapidly becomes widely infiltrated with tuberculous products, which quickly undergo caseation. The articular cartilage is destroyed and suppuration takes place. This leads to the formation of large burrowing collections of pus and complete disorganisation of the affected joint, so that amputation is the only course that can be recommended. In other parts—e.g., the testis or the lymphatic glands—early suppuration, with breaking down, occurs. The unfavourable progress in these cases is so constant that I do not myself remember to have seen repair take place in a tuberculous joint in any person over fifty years of age. The disastrous results that will probably follow when one of the large joints, such as the hip, is involved was well shown in the following case, which came under notice five or six years ago. A woman, aged fifty-five years, had tuberculous disease of her hip-joint, which was, for the first few weeks, considered to be, and was treated as, "sciatica." Afterwards the case was treated with absolute rest, secured by a Thomas's splint and weight extension. The joint, however, grew steadily worse; in four months suppuration occurred, and matter was found both in Scarpa's triangle and under the tensor fasciæ femoris, and later under the glutei. The limb became rotated outwards and shortened, and at last it became clear that the head of the femur and the upper border of the acetabulum had been absorbed, so that the upper end of the femur could be pushed up and pulled down on the

Hosted by Google

pelvic wall through a range of three inches. Thus this joint within about eight months became a complete wreck. The patient died a few weeks later from phthisis and exhaustion. The best treatment, although it will often be found of little avail, is from the first to place the affected joint at absolute rest; to secure the best conditions for preserving the patient's general health; to open abscesses as they form, with the most rigid precautions against septic changes in the wound; and to resort to amputation when it is found that the progress of the case is in a persistently downward direction. Amputation, if means are taken to prevent hæmorrhage, and if an aseptic condition is maintained, will be perfectly well borne in the case of all the smaller joints and often of the knee. (In the case of the hip, of course, the idea of amputation cannot reasonably be entertained, nor would excision be a proper step.) After amputation has been performed the patient may, as I have several times seen, recover and long maintain perfectly good health. The list of cases of which I have given the foregoing brief account conveys a repetition of Sir James Paget's statement that there are no structures which in the young appear to be "seats of election" of scrofula (or, as would now be said, of tuberculosis) in which the affection is not met with in people over sixty years of age.

Another form of tuberculous disease which is seldom, if at all, referred to in the current manuals of clinical surgery is "subcutaneous ulceration"—a name which, like that of "senile scrofula" (now tuberculosis), we originally owe to Sir James Paget. The nature and course of this affection will be most readily indicated by two or three examples.

CASE 7.—Two months ago a boy, aged nine years, was admitted into St. Bartholomew's Hospital with a sinus on the inner side of his popliteal space and some ill-defined thickening over the neighbourhood of the internal condyle of the femur. These appearances suggested that the case was one of tuberculous disease of the lower end of the femur, attended with suppuration. On passing a probe, however, through the sinus, no bare bone could be detected, and, indeed, it was apparent that the probe nowhere passed through the deep fascia, but that it ran easily in various directions close beneath the skin, which, over the most prominent part of the internal condyle, was scarcely thicker than writing-paper. The probe also passed in the subcutaneous tissue nearly half-way down the leg, and its point moved horizontally through a considerable area, showing that the skin was widely detached. The nature of the case as one of wide undermining of the skin by "subcutaneous ulceration" was now clear. The whole of the undermined area was therefore exposed by free incision of the skin; the flaps thus formed were raised and turned back; the granulation tissue was thoroughly scraped away with a Volkmann's spoon; the wound was dusted with iodoform, and the flaps were replaced and fixed by sutures. Sound healing by primary union occurred except in the immediate neighbourhood of the original sinus. Here an exuberant crop of tuberculous granulation tissue remained, and a second scraping was necessary. Soon afterwards sound healing took place.

CASE 8.—A boy, aged ten years, was admitted some years ago into the Hospital for Sick Children, Great Ormond-street, with three sinuses, three or four inches apart, over the tibia. The orifices of these sinuses were filled with protruding granulation tissue, and their general appearance, together with some swelling of the soft parts, seemed to indicate plainly enough that the case was one of necrosis of the tibia. On proceeding to operate, however, I found that the deep fascia was everywhere intact; but the subcutaneous tissue for some distance around was converted into granulation tissue, so that the skin was completely undermined. In places it was very thin. Free incisions were made, the granulation tissue was scraped away, and the flaps were replaced and sutured. The wound healed in about three weeks.

CASE 9.—A youth, aged eighteen years, was in St. Bartholomew's Hospital two years ago with four sinuses over his occipital region which from their position seemed at first sight to suggest necrosis of the occipital bone. These sinuses had existed for about nine months. On examination it was found that the bone was nowhere exposed and that the sinuses led down merely to the areolar space beneath the occipito-frontalis. The pericranium was quite normal. The probe travelled freely in all directions over a nearly circular area about three inches in diameter. Incisions were made and the scalp over this area was turned up, the granulation tissue was scraped away, and the wound was treated as in the former cases. Healing quickly occurred, and when the patient left the hospital, three weeks later, there remained only three short sinuses which promised to be soundly healed in the course of a week or two.

The explanation of this particular form of tuberculous disease appears to be the following. When the tuberculous process is established in the subcutaneous tissue it extends in a horizontal direction, because the subcutaneous tissue is loose, vascular, and easily invaded, whereas both the skin and the deep fascia, especially the latter, owing to their comparative firmness and toughness, tend to withstand infection. The same fact is illustrated by the ordinary undermining of the skin in superficial tuberculous ulceration. It is illustrated also by the fact that in rodent ulcer the process extends in the subcutaneous tissue further than it does in the skin itself, so that for the complete removal of this disease it is necessary to cut well beyond the limits to which the skin appears to the naked eye to be involved. In fact, in subcutaneous ulceration, as in other instances, the undermining of the skin is due to the fact that the process of infection spreads most readily in the direction of least resistance.

THE

PROGNOSIS OF PNEUMOTHORAX, WITH SOME STATISTICS AS TO MORTALITY AND DURATION, AND AN ACCOUNT OF A SERIES OF CASES OF RECOVERY.[1]

BY SAMUEL WEST, M.D. OXON., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN, ETC., TO ST. BARTHOLOMEW'S HOSPITAL; SENIOR PHYSICIAN TO THE ROYAL FREE HOSPITAL.

PNEUMOTHORAX is a subject which does not appear to have attracted of recent years as much attention as might have been expected from the importance of the subject. In the Bradshaw Lecture at the Royal College of Physicians of London in 1887 I drew attention to several points of theoretical and clinical interest. The present communication is of a more practical character and deals with the prognosis of the affection. Prognosis is without doubt the most difficult part of clinical medicine, for it not only necessitates profound knowledge of the natural history of the disease and of the general laws to which it is subject, but it requires also the power of appreciating at their true value the peculiar features of the individual case and of determining the extent to which the general laws must be modified to suit the particular instance. I must premise that in this paper I am dealing only with the cases which are ordinarily indicated by the term "pneumothorax" and not with cases in which the air has gained access to the pleura through a large opening in the chest walls produced by operation or injury. Before approaching the question of prognosis in pneumothorax it is necessary to refer to what is known as the general course of the disease so far as it is indicated by its mortality and duration. Upon this subject my observations are drawn from three sources: (1) a series of 101 cases from the records of the Chest Hospital, Victoria-park, published by me some years ago; (2) a series of 45 cases taken from the registers of St. Bartholomew's Hospital; and (3) a series of 21 cases which have been under my own personal observation. These last two series have not yet been published. Of the first series of 101 cases 66 died, giving, roughly speaking, a mortality of 2 out of 3; but of these 101 cases in 74 the pneumothorax developed in the hospital, of which 57 died—i.e., 77 per cent.; while of the 27 cases of pneumothorax which were admitted into the hospital with pneumothorax only 9 died—i.e., 33 per cent. The difference between the two sets of figures is to be explained by the fact that the mortality from pneumothorax is greatest in the first few days which follow the onset, while the latter group of cases consists entirely of those who had survived this period for varied lengths of time. The rate, therefore, given by the first group probably approaches more nearly to the true mortality of the

[1] A paper read before the Medical Society of London on Jan. 11th, 1897.

Hosted by Google

disease than the other. In the second series of 43 cases 26 died, giving a rate of 60 per cent., and this is also the rate yielded by the third series of 20 cases under my own care. We may conclude, therefore, that the general mortality of pneumothorax ranges somewhere about 70 per cent.—i.e., rather more than 2 cases out of 3 die. Saussier's figures give a much higher rate—viz., 131 out of 147, or about 90 per cent.

Duration.—In the first series of 101 cases the duration is known exactly in 39 and approximately in 37 others. Of the cases in this latter group the pneumothorax occurred in 10 patients during their stay in the hospital; but the patients recovered sufficiently to leave, so that the terminus *ad quem* is not fixed. In the 27 other cases the patients were admitted with it, and in many of these the terminus *a quo*—i.e., the date of onset—was not quite certain. Altogether pneumothorax occurred 74 times in patients while they were in the hospital, and in these cases the duration is known in 31 exactly and very nearly in 8 more; while in the remainder all that can be said is that the disease did not last less than a certain time—that is to say, the length of the stay in the hospital.

Table showing duration in 76 cases—39 known, 37 approximate.

Months.	Weeks.	Days.	Duration known (39 cases).	Approximate duration (37 cases). Admitted with pneumothorax. Died.	Left with it.	Developed pneumothorax in hospital and died.	Total 76 died.

Of the 39 cases in which the duration is known 10 patients died on the first day, 2 within twenty minutes and thirty minutes respectively of the attack, and the other 8 within a few hours. In all, 18 had died by the end of the first week and 21 by the end of the fortnight, to which may be added 8 more cases in which the duration cannot be quite determined, though it was certainly less than fourteen days, making thus 29 out of 39 cases which were fatal within the fortnight—nearly 75 per cent.; in other words, 3 out of every 4 cases. Six more died within the second fortnight, making thus 35 deaths out of 39 cases within the month, or 90 per cent.—a figure which exactly agrees with Saussier's statistics already referred to. I believe these statistics are too high for the results of the present day, as will be seen when I refer to the more recent series of my own personal cases. Of the remaining 10 per cent., or whatever the exact figure may be—i.e., of those patients who did not die within the month—the duration was considerably longer, many weeks, occasionally many months, and some patients recovered completely. Of the 35 cases in which the duration was uncertain 9 were admitted with pneumothorax and died in the hospital, 10 developed pneumothorax in the hospital and left at varying dates after the attack, some of whom were known to have died subsequently at their own homes, while 18 patients were admitted with pneumothorax and left with it. Of this second group, taking all the cases together, 10 died within the first month, 8 more within the second, and 2 more within the third, making 19 in all. Taking the 2 series together, of 74 cases 45 died within the month—i.e., 60 per cent.; 9 more died within the second month, making 71 per cent. Of the remainder the duration may be much longer and some may recover; 7 were known to be alive at the end of the third month, 1 at the end of the fifth, and 1 at the end of the ninth. Of the 20 cases which were under my own care, 12 only died and 8 recovered, giving a mortality of 60 per cent., which is exactly that which the records of St. Bartholomew's Hospital for the last fourteen years also yield.

The cause of death.—The real mortality from pneumothorax is difficult to arrive at, for it often happens that the patient gets over the pneumothorax, possibly even recovers completely from it, and yet dies before long either from the diseases which caused the pneumothorax or from the results to which the pneumothorax indirectly led. The causes of death must be dealt with in three groups: the first, in which death is the direct result of the pneumothorax itself; the second, in which it is the indirect result of it and due to the complications which follow—e.g., empyema; the third, where it is the result of the original disease—e.g., phthisis—to which the pneumothorax itself was due, the pneumothorax being at the most but a more or less serious complication, accelerating possibly the end, though not itself entirely responsible for the result.

1. The great majority of the fatal cases of pneumothorax die, as already stated, within the first few days of the disease; nearly one-half—46 per cent.—die within the first week. Of the cases that were fatal during the first fortnight, no less than one-third died on the first day, two within twenty and thirty minutes respectively of the onset of the disease, and the majority of the others within a few hours. Where death is the direct result of pneumothorax the cause of death is suffocation. This is due in most cases to the sudden embarrassment of the respiration and circulation consequent upon the disease, and it is not so much the amount of change as the suddenness of it that is the cause of the grave symptoms, so that if time be given for the circulation and respiration to adjust itself the urgency of the symptoms may pass off, and thus it may be stated that every hour the patient keeps alive the better the chances are of his passing safely through the initial dangers. Another and different cause of suffocation, mechanical rather than physiological, lies in the sudden discharge of the contents of cavities into the air-tubes which get sucked into the remaining lung and thus choke the patient. I have seen this occur more than once. Lastly, there is a class of case in which death may be called sudden or immediate and may be referred to shock. This is very rare and I have never seen an instance of it myself. Lebert describes a case in a young medical man of the age of twenty-eight years. Of the two cases in which the patient died within twenty minutes and thirty minutes respectively of the onset of the disease the cause of death in each was acute suffocation and not shock. The initial dangers can, no doubt, be greatly diminished by the early recognition of the disease and its appropriate treatment, and it is probable that the diminished mortality of pneumothorax in recent years is due to improved diagnosis and treatment.

2. Where death follows at a later period it is often the result of the effusion consequent on the pneumothorax. The effusions are, roughly speaking, serous in one-third of the cases, sero-purulent in another third, and purulent in the remaining third; where the effusion is purulent, sooner or later the side has to be opened, either because the empyema points or discharges itself or because it is deliberately incised. The condition then becomes one of an open empyema, and under unusually unfavourable conditions, for, owing to the prevailing prejudice against early incision in pneumothorax, the lung has been probably bound down and cannot consequently expand, and, secondly, because of the complication of the effusion with more or less extensive tuberculous disease of the lung. Any way, the patients die usually from asthenia, the result partly of the prolonged discharge and partly of the phthisis.

3. In the third group of cases it is not from pneumothorax that the patient dies, but from the original disease which produced the pneumothorax. This is usually phthisis. In

Hosted by Google

many of these cases the pneumothorax is nothing more than a more or less grave complication, which may accelerate the end, though it is not of itself the cause of death. In other cases, though the patient is dying actually from phthisis, the pneumothorax which has been produced may get well completely.

Prognosis.—In dealing with prognosis we must presume that we have a case of complete and not of partial pneumothorax to deal with, for localised pneumothorax is comparatively an unimportant affection. Also, that when pneumothorax results from the discharge of an empyema through the lung or externally through the chest walls the prognosis is that of empyema and not of pneumothorax, and therefore relatively more favourable. The three considerations usually embraced by the common term "prognosis" require, in a case of pneumothorax, to be separately dealt with. They are, first, the immediate risk to life; secondly, the possible duration of life; and, thirdly, the chance of ultimate recovery. Many of these points have been already incidentally referred to in treating of the mortality and duration of the disease.

1. *As regards the immediate risk to life.*—This is always great, and greatest during the early hours and days of the disease, as has been already shown, so that, speaking generally, other things being equal, the chances of life increase in proportion to the period which elapses from the onset; but in any given case the actual prognosis at the time must be determined by many other considerations, of which the following are the most important. (*a*) The urgency of the symptoms; (*b*) the effect produced upon the opposite lung and the amount of previous disease in it; (*c*) the effect upon the heart; (*d*) the general strength of the patient; and (*e*) the nature of the cause—e.g., injury, phthisis, gangrene of the lung, &c.

a. The urgency of the symptoms. This is measured practically by the amount of dyspnœa and cyanosis, which is often so extreme that unless relief can be given the patient must die. The greater the relief given by paracentesis, and the longer the interval between successive paracenteses, the better the immediate prognosis.

b. The condition of the opposite lung. This lung, being overworked, may not be equal to the strain upon it, and if it gives way the physical signs of congestion (i.e., of bronchitis) will manifest themselves. Thus it is that rhonchus and sibilus become signs of very bad omen. The amount of previous disease in the lung is important, inasmuch as the lung is rendered thereby less able to meet the extra demands made upon it.

c. The effect upon the heart; for the difficulty of circulation throws extra work upon the right side of the heart, and if this exceeds a certain amount dilatation and its consequences will be the result—a result which will be the more likely to follow if the heart be previously diseased.

d. The general strength of the patient. This is important in two respects: first, in so far as it affects the muscular power, for this is taxed, on the one hand, in the respiratory muscles, which have so much extra work to do, and, on the other hand, in the heart, which in a weakly patient is all the more likely to give way rapidly; secondly, in so far as it affects the general stamina and powers of endurance of the patient.

e. Lastly, a good deal will turn upon the disease which has led to the pneumothorax. In the vast majority of cases this is phthisis, and this class of case may be taken to represent the average. As giving a prognosis better than the average may be instanced cases of pneumothorax following simple injury, such as a stab or a fractured rib, and as giving a still worse prognosis, cases of gangrene of the lung, for these are almost invariably fatal.

2. *As regards the duration of life.*—If the urgent initial symptoms have passed off the prognosis will depend upon the general strength of the patient and upon the nature of the disease with which the pneumothorax is associated, but principally upon the complications to which the pneumothorax may lead—i.e., upon the occurrence of effusion and its character.

3. *As regards recovery.*—Speaking generally, the number of recoveries in pneumothorax is small. Most statistics give a more or less complete recovery in not more than 10 per cent. The figures derived from the St. Bartholomew's records yield over 25 per cent., and my own cases are even more favourable still. In my own 20 cases 5 recovered completely and remained well for long periods; in 3 the recovery from pneumothorax was complete, but the patient died subsequently from phthisis, and in 3 others recovery was incomplete. Besides these I have seen 1 other case in consultation in which recovery was complete, and the patient has remained well for many years. The most favourable cases are those in which no effusion takes place. The air is then simply absorbed, and often with considerable rapidity. Of this there were 4 instances, and to these may be added the consultation case referred to. In another group of cases effusion forms, but it is serous, and recovery then takes place with or without paracentesis, just as it does after ordinary serous effusion. Sometimes the fluid, after being removed by paracentesis, does not re-form, but the air remains for some time longer, though it is ultimately absorbed also. In other cases the air is absorbed first, fluid takes its place, the case becomes one of ordinary serous effusion, and recovers in the same way. When the effusion is purulent the prognosis is much more serious, but even some of these cases in time recover. In one of my cases expectoration took place through the lung, and in the end the patient recovered completely. In one other the pus was discharged externally and recovery was imperfect, the patient being left with a discharging sinus for more than twelve months, by which time extensive phthisis had developed from which the patient soon after died.

I now pass to the account of the cases of recovery, which number 11. In 5 no effusion formed; 1 was dying from phthisis; 1 had phthisis, but was living some months after recovery; in the others no definite signs of phthisis developed. In 4 there was serous or sero-purulent effusion; of these four 1 was under the tuberculin treatment for phthisis at the time, and had two attacks at a short interval on the same side, but gave no definite signs of phthisis; 1 had a second attack on the other side six months after recovery from the first; 1 got completely well; the fourth left with the effusion, having refused operation. Of the 2 cases with purulent effusion, 1 recovered with a fistula, but died from phthisis twelve months later. The other expectorated pus for some time, but refused operation.

CASES OF RECOVERY.

A.—Without Effusion of Fluid.

CASE 1. *Acute phthisis; pneumothorax of the left side developing in the hospital; complete recovery in five weeks; rapid progress in the phthisis, and death subsequently at home from phthisis.*—The patient, a woman aged nineteen years, was admitted into the Chest Hospital, Victoria-park, with acute phthisis of the right apex and with some early mischief on the left side also. The disease was probably of about three months' duration. Six weeks after her admission (April 7th) she was seized one morning with pain in the left side and some shortness of breath. The symptoms were not very urgent, but she was found on examination to have pneumothorax of the left side with considerable displacement of organs. No fluid formed, the air was absorbed, though somewhat slowly, and by May 14th (i.e., five weeks from the onset) the two layers of the pleura were in contact in most places and dry friction was heard, and by the end of the month (i.e., seven weeks from the onset) the condition of the side was the same as before the pneumothorax, the heart's apex was in its normal place, and over it a well-marked pleuro-pericardial friction was present, which persisted for a short time and then also disappeared. The lung re-expanded completely, and nothing was left but a little impairment of percussion at the base behind. There had been no evidence at any time of fluid and succussion had been entirely absent. The temperature was hectic throughout, and was completely unaffected by the occurrence of pneumothorax. On July 10th she left the hospital at her friends' request—i.e., about twelve weeks after the onset of the pneumothorax. The phthisis had all the time been making very rapid progress, and a few weeks later caused the patient's death.

CASE 2. *Pneumothorax of the left side, without definite symptoms at the time of onset, without effusion, and complete recovery.*—A man, aged forty-six years, was sent up to me by Dr. Parry-Jones. About six weeks before admission he was at work and felt a pain in the left side, which made his breath somewhat short. The dyspnœa was not severe, so that he was able to continue his work, and he remained at work until shortly before I saw him, and with no special discomfort, except that he found his breath a little shorter than usual on effort. For this he consulted Dr. Parry-Jones, who found that the patient had pneumothorax, and sent him up to the hospital to me, although the man did not think himself ill enough

Hosted by Google

to be placed upon the sick list. The whole of the left side was tympanitic to percussion almost to the very margin of the ribs; the heart was displaced, so that impulse was felt below the right nipple, and the pleura extended one and a half inches to the right of the sternum opposite the third rib. There was no bell sound or succussion; the breath sounds were absent everywhere except in the interscapular space and a little below this, and here the breathing was exaggerated and some metallic tinkling heard. The movements of the side were quite free. I made the following note at this time: the patient had pneumothorax of the left side; the amphoric breathing and metallic tinkling were probably produced in the lung, but the opening was itself closed; the free movements of the side indicated that the lung was not bound down, but expanded readily on inspiration. On Sept. 3rd the patient was quite well, the air was completely absorbed, and the lung re-expanded. The following note was then taken: the percussion was equal on the two sides, the cardiac dulness was in its normal place, the stomach resonance was a little higher than usual, and over a small spot at the base behind there was probably a little pleurisy, for the percussion was slightly impaired, the breath sounds were feeble, and some fine crepitation—probably pleuritic friction—was heard on deep inspiration; i.e., except for this the voice and breath sounds were normal over the whole side. The patient gained 14 lb. in weight in the hospital, and looked and felt quite well. Once or twice during his stay he had a little hæmoptysis, from which he had suffered occasionally before his attack. Dr. Parry-Jones has been kind enough to send me the following report of him this year, ten years since his attack of pneumothorax: "I find the patient has been at work ever since 1886 and has had no illness. He appears to be now in good health and his chest is in every way normal. I hear, however, from a doctor who saw him a few weeks ago that he had then a very slight attack of pleurisy on the left side, but of this there is no sign now.

CASE 3. *A man under treatment for possible phthisis who developed right pneumothorax; complete recovery in six weeks; well twelve months afterwards.*—The patient, a man, aged twenty-four years, had been under observation for some time suffering, it was supposed, from phthisis, of which, however, there were no definite physical signs. On Nov. 7th he was suddenly seized with severe pain on the right side with much dyspnœa. He was taken to the Royal Hospital for Diseases of the Chest, where Dr. Hensley drew off a large quantity of air next day by means of the aspirator. The patient left that hospital and came under my care four days later. The dyspnœa had disappeared, but the physical signs of pneumothorax were obvious. There was no distension of the side to sight or touch, but there was a good deal of subcutaneous emphysema which had followed the paracentesis. The heart was displaced, so that the apex beat was felt one inch outside the left nipple line; there were loud bell sounds and amphoric breathing over the whole side; succussion was absent. On the 15th the physical signs were the same; the bell sounds and amphoric breathing were well marked. On the 20th the physical signs were unaltered, but the apex of the heart had returned to the nipple line. On Dec. 9th the bell sounds had disappeared and did not subsequently return; the amphoric sounds were very weak, and the heart's apex was within the nipple line. On the 20th the right side seemed to be a little flatter and to move somewhat less than the left, but otherwise to be normal; the amphoric breathing had also disappeared and natural breathing was heard over the whole side, back, and front, while the apex of the heart was in its normal place. Thus within six weeks the air had been completely absorbed and the lung had re-expanded. The patient seemed perfectly well and was discharged. He was often seen subsequently, and though troubled from time to time with cough remained in better health than usual, and, indeed, gained flesh. With the exception of a little streaky hæmoptysis five months after his discharge he remained perfectly well, and was known to be in good health more than a year after the occurrence of the pneumothorax.

CASE 4. *Pneumothorax of the right side, probably the third attack; no fluid; complete recovery.*—The patient, a man, aged twenty-two years, was delicate as a boy and was subject to cough, but of recent years had grown stronger, and is now fairly active and strong. He was in his usual health until August, when, whilst walking, he had a sudden attack of pain just above the right clavicle and felt a bubbling sensation in the right side and the breath suddenly became short. After this he noticed that he had a "churchyard cough," but though he was able to keep to his work he was obliged to avoid all violent exercise for about a fortnight, when he got quite well. In the beginning of November—that is to say, four months later—after a game of football in which he was on more than one occasion heavily charged, he became again short of breath. This lasted about a month, but in the end he again got perfectly well. He remained well until just before Christmas (Dec. 23rd), when suddenly, after getting up in the morning, the shortness of breath again appeared and continued so until his admission into the hospital on Jan. 4th. He was then found to have pneumothorax of the right side. The chest was fairly well developed, but was a little flat in the upper part; the heart's apex was in the left nipple line, but the pleuritic hyper-resonance extended across the sternum for nearly an inch to the left. On the right side the breathing was amphoric in character, but no bell sound was obtained and no succussion. The liver dulness was at the lower edge of the seventh rib, so that the tympanitic percussion did not extend exactly to the costal arch. The diagnosis made was that the patient had had pneumothorax and that the air had been partly absorbed. He presented no symptoms; the temperature was normal and he seemed well, so that on the 17th he was allowed to get up, and on the 24th was up all day. He could get about without any shortness of breath and the physical signs were not much altered. On Feb. 5th it was noted that the shape of the chest was symmetrical; movements were free, but there was a little more expansion on the left side than the right on deep inspiration; the liver stood at the sixth rib in the nipple line on the right side; cardiac dulness was normal in place and size; the percussion note was still a little hyper-resonant on the right side, the left was normal; the breath sounds were vesicular and audible down to the base, though a little more distinct at the apex than elsewhere; a little fine crepitation in the mid-axillary line was heard when some pain had been complained of. The patient was seen many times subsequently and was known to be in excellent health for many months, when he became lost to observation.

CASE 5. *Pneumothorax in an apparently healthy girl; no effusion; complete recovery.*—This was a case seen in consultation and is not included in my series. The following account of the case was sent to me by Dr. Waldo of Clifton, Bristol: "The patient, a girl, aged fifteen years, thought she felt something give way in her right side when dancing. She was first seen by me on Aug. 14th, 1890, when she complained of a sharp pain under the right collar-bone. The heart's apex was half an inch outside the nipple line on the left side, and there were the ordinary signs of pneumothorax, but no succussion. Shortly afterwards you saw her and recommended that she should stay in bed for many weeks. I have a note that on Oct. 6th, 1890, the heart's apex was in its normal position and the respiratory murmuring equally good on each side. The patient had never spat any blood and there were no signs of tubercle. Her weight was 6 st. 4 lb. I have seen the patient only a few times since, as far as I can recollect, and I have every reason to think that the patient is still in good health."

I recorded one of the cases just described (Case 3) in the Transactions of the Clinical Society of 1884, and I collated a series of 24 cases of this kind,[2] nearly all in males. The majority of these cases made a rapid recovery; some were well in a few days, others in a few weeks; the longest took eleven weeks. The probable cause was specified in 18; 4 were due to phthisis certainly and 4 more probably, 3 were attributed to emphysema, 2 followed over-exertion in previously strong, healthy persons, and 3 were traumatic. In 4 only was mention made of evacuation of air by puncture.

(To be continued.)

[2] Cf. also Gaillard, Archives Générales de Médecine, 1888, p. 286, with many of the same cases recorded.

THE BATH ROYAL MINERAL WATER HOSPITAL.—The annual meeting of the governors of this hospital was held on May 1st. The report stated that 1263 patients had been treated in the institution during 1896 and that the daily average in the hospital was 142, their average stay being 47½ days each. Fifty-two of the patients were cured and 959 greatly benefited. General Mainwaring was again elected president.

SKIAGRAM OF THORACIC ANEURYSM.[1]

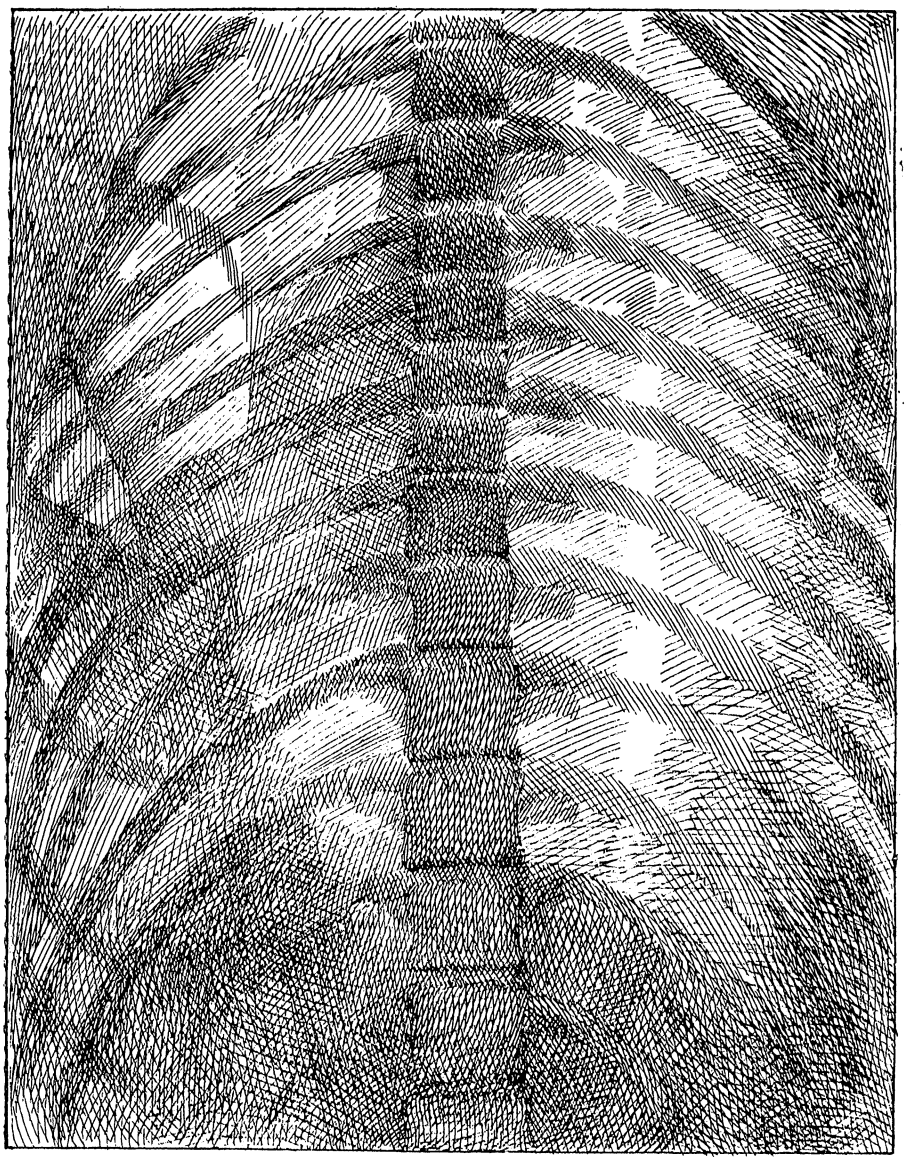
BY JAMES J. YOUNG DALGARNO, M.B., C.M. ABERD.,
AND
ALEXANDER RUDOLF GALLOWAY, M.B., C.M. ABERD.,
MEDICAL ELECTRICIANS, ABERDEEN ROYAL INFIRMARY.

ON Jan. 6th of this year Dr. Edmond sent to the Electrical Department, from his wards in the Aberdeen Royal Infirmary, a patient whom he suspected to be suffering from an aortic aneurysm, with the request that a skiagram should be taken in order to confirm, if possible, the diagnosis. On examining the patient by means of the fluoroscope, the shadow of the heart at its upper part was seen distinctly to encroach on the clear area of the right lung. This encroachment had a curved border, with its convexity towards the patient's right. Having observed this abnormality, and being unaware that any successful skiagram of a thoracic aneurysm had been reported, we proceeded to skiagraph the patient's thorax in the manner to be subsequently described. For the following short notes of the case we are indebted to Dr. Edmond.

"The patient was a married man, aged forty-four years. There was nothing of special interest in either his family or personal history. He denied having had any specific disease, but acknowledged to alcoholic excess. He stated that about two months previously to his admission on October 27th, 1896, to the Aberdeen Royal Infirmary he began to suffer from cough and pain in the chest and neck. He lost flesh and strength, and was obliged to cease work and to apply for admission to the infirmary. On admission he complained of cough with scanty expectoration, pain across the chest about the level of the third ribs, shooting into the neck and arms, and shortness of breath on exertion. On inspection his chest appeared to be barrel-shaped, with expansion deficient, particularly on the left side. There was no bulging anywhere visible, and no undue pulsation visible or palpable, either in the chest or neck. On percussion

FIG. 1.

Drawing from skiagram of abnormal thorax. The shadow of the aneurysm is seen lying in front of the spine and extending from the base of the second to the seventh dorsal vertebræ and head of the seventh rib.



[1] Exhibited before the Aberdeen Medico-Chirurgical Society.

Hosted by Google

the note was found to be hyper-resonant over the whole of the front and back of the right side, and rather flat over the corresponding parts of the left. Over the manubrium sterni and extending to the left there was a slightly dull note. On auscultation the breath sounds over the front and back of the right side were loud and harsh, with prolonged expiratory murmur. Over the front and back of the left side the breath sounds were all but extinguished. A few dry rhonchi were heard on the right side. His voice was hoarse and his cough had a distinctly laryngeal tone. The heart's impulse was feeble to palpation and not visible. The area of cardiac dulness was about normal. At the apex the heart's sounds were feeble and free from murmur. At the base, in the pulmonary area, they were scarcely audible; in the aortic area they were abnormally loud, particularly the second, which was markedly accentuated. The pupils were equal in size and reacted freely to light. The left radial pulse was weaker than the right. There was well-marked tracheal tugging. His larynx was examined by Dr. McKenzie Booth, who reported paralysis of the left vocal cord. During his stay in hospital he was treated with large doses of iodide of potash and left somewhat improved. We heard that he died on Jan. 16th, 1897, some weeks afterwards, from lung complications, but found it quite impossible to obtain the permission of the relatives for a post-mortem examination."

The skiagram of the aortic aneurysm was taken while the patient lay on his back upon a 20 × 16 in. professional Cadett plate. The ordinary focus-tube was used at a distance of fifteen inches from the plate and an exposure of thirty-five minutes was given. The 8-inch spark Rhumkorff coil was actuated by five E. P. S. accumulators of about two volts each. On examining the skiagram of the suspected aneurysm the curved shadow on the clear area of the right lung, observed by means of the fluoroscope, is at once seen, along with a larger extension of the same shadow to the left, this latter part of the shadow merging gradually into the normal shadow of the heart. The abnormal shadow is seen to lie in the upper part of the chest, in front of the spine, and extends from the base of the second to the lower part of the seventh dorsal vertebra (Fig. 1). On the right side the gradual curve is seen vividly against the clear lung, commencing at the articulation of the third rib with the spine, curving outwards to a point two and seven-sixteenths inches from the mid-spine, and then inwards to its lower limit at the spinal articulation of the eighth rib.

FIG. 2.

Drawing from skiagram of a normal thorax for comparison.

Hosted by Google

A darker shadow lies half an inch inside this outline and follows the same shape of curve. On the left side the lower limit of the shadow is the same as on the right, but its curve is greater, extending to a point three inches from the mid-spine. The upper limit of the curve is lost at a point two and three-quarter inches from the mid-spine opposite the base of the second dorsal vertebra. On the right side the inferior angle of the scapula is well seen between the seventh and eighth ribs, four and a half inches from the mid-spine. The spine of the scapula is seen running from between the third and fourth ribs upwards and outwards towards the shoulder-joint. On this side, also, the lung space is much clearer and the interspaces between the ribs wider than on the left. On the left side the heart shadow (though indistinct, as the patient was lying on his back) is seen extending from the point of maximum curve of the abnormal shadow downwards and outwards to the tenth rib. On this side it is interesting to note that the lung space is much duller in appearance and the interspaces between the ribs narrower, because during life physical examination proved that breath-sounds were almost absent in this lung. The spine and inferior angle of the left scapula can also be seen. The shoulder articulations and shafts of both humeri are visible. The front curvatures of some of the ribs on both sides also appear as large ill-defined shadows, crossing the lung space at right angles to the direction of the ribs at the back. The upper surface of the liver appears very distinctly on the right side. For purposes of comparison a normal thorax of about the same dimensions as the one with the aneurysm was skiagraphed under precisely similar conditions, and the points of interest in it are as follows.

Normal Thorax.—In the upper part of the skiagram no shadow is seen on the right side, nor on the left above the level of the fifth dorsal vertebra (Fig. 2). In these regions the lungs are equally clear on both sides, and the interspaces between the ribs equal in size. The indistinct shadow of the heart is seen on the left, extending from the upper part of the fifth dorsal vertebra downwards and outwards in almost a straight line to a point about five inches from the mid-spine on a level with the lower part of the tenth dorsal vertebra. A darker shadow is visible, leaving the former one at the sixth rib, with a curve which forms its lower border, and reaches to the middle of the eighth dorsal vertebra. This darker shadow is probably the base of the heart. In this skiagram also the spines and inferior angles of the scapulæ are visible.

A CASE OF INJURY TO THE SHOULDER FROM THE SCHULTZE METHOD OF ARTIFICIAL RESPIRATION.

BY GORDON C. BARKER, M.A. CANTAB., M.D. BRUX., M.R.C.S. ENG., L.R.C.P. LOND.,
HONORARY PHYSICIAN TO THE BRIGHTON, HOVE, AND PRESTON DISPENSARY, BRIGHTON.

ASPHYXIA neonatorum is generally treated in Germany by the Schultze method of artificial respiration, which is not in such common use in this country; but it is taught and practised at the Rotunda Hospital, Dublin, and from experience there and subsequently I regard the method as prompt and effective.

The case I now record of injury to the shoulder from the Schultze method is perhaps unique; but it shows the possibility of accident and the necessity for most careful manipulation. The facts are as follow: The child was born at the "klinik" of a celebrated obstetrician in a German city, near which the mother—an Englishwoman—was staying. She was, however, attended by his assistant, also a specialist of high repute. It was fortunate that she was in such good hands; it proved a prolonged and difficult instrumental case, the child, a boy weighing 11 lb. Artificial respiration was necessary; the Schultze method was used and it revived the child. For forty-eight hours he was continuously fretful, and neither slept nor took the breast. There was no explanation of this fretfulness until extensive ecchymosis behind the left shoulder and in the axilla drew attention to the arm, which hung limp and flaccid. When the mother and child left the "klinik" after the usual interval, the arm still hung loosely from the shoulder, and the infant had shown no disposition to use it. Careful examinations had revealed no fracture, dislocation, or other radical injury, and it was believed that nothing existed which time would not remedy. Unfortunately, these hopes were not fulfilled. At three months old the child could make some limited movements with the arm and weak, awkward efforts with the hand, but rigidity at the shoulder-joint had supervened on the primary flaccid limpness. During the seven months following the child's birth the parents were travelling, and after leaving the "klinik" had only once had an opportunity of getting professional opinion about the arm. The child was then four months old, and they were becoming very uneasy; but a medical man, after superficially observing the child without having him unclothed, again lulled their anxiety by treating the matter lightly, and repeating the hope that all would come right with time. They were but too pleased to accept this opinion, particularly as the boy was the long-desired successor to five daughters and remarkably fine and healthy withal. When he was seven months old they had again become so dissatisfied that they had determined, by a friend's advice, to go to London for Mr. Pearce Gould's opinion. They had then come to Brighton, and a brief postponement was caused by severe illness in the family. The baby was eight months old when the mother one day asked me to tell her what I thought of his left arm. While I engaged his right hand he eagerly clutched at my proffered pencil-case with his left hand and arm in a most unnatural position. It was very evident that there was something radically amiss, and the next day I made a careful examination with the child stripped. On inspection from the front the following points were noticed. The whole arm was strongly rotated inwards, adducted, and drawn forwards. So constant was this position that the skin in front of the axilla was folded into a permanent, deep sulcus. Compared with the right the left deltoid was very flat and deficient, likewise the biceps. Inspection behind showed the humeral head and scapular spine unduly prominent, owing to the deficient size of those muscles, which normally make these bony prominences indistinct. The triceps was also undersized. The forearm muscles were not so noticeably undeveloped, and measurements proved the humerus to be only slightly shorter than its fellow. Examination showed that the relations of bony points about the shoulder and elbow were normal, with the exception that the head of the humerus was, perhaps, slightly tilted back towards the posterior lip of the glenoid cavity. The tendon of the pectoralis major was large, tense, and contracted, and kept the arm powerfully rotated inwards, adducted, and drawn across the chest. Attempts to overcome it were futile and caused immediate suffering. When by engaging the sound arm the child was induced to grasp with the other at any attractive article he habitually flexed and internally rotated the arm more excessively, and by bringing the forearm pronators into extreme action carried the little finger and the ring finger uppermost and grasped with them only. These two fingers were well developed, whereas the unused other three were comparatively small. By my advice Mr. Pearce Gould was at once consulted. He concluded from the history, with the important fact of the primary extensive ecchymosis behind the shoulder and in the axilla, and from the condition he found—great wasting of the muscles in the infra-spinous fossa of the scapula, with thickening at the back of the upper end of the humerus—that the infra-spinatus and teres minor muscles had been ruptured when the Schultze method was used, and that the deformity had been gradually produced by the unopposed and naturally stronger internal rotators, the pectoralis major in particular. He advised the breaking down of adhesions and the stretching of contracted tendons by free movements under chloroform, to be followed by massage, movements, and electricity. In a few days' time I administered chloroform, and Mr. Pearce Gould thoroughly carried out these operations and fixed the arm in extreme external rotation by means of broad strapping passed round the limb and then round the chest. On the four consecutive days I repeated the free movements and re-strapped the limb, with the child anæsthetised. The operation then became easier and less painful, and anæsthesia was dispensed with. Mr. Pearce Gould had not given a very favourable prognosis, but yet held out hopes of substantial improvement should after treatment be persistent and thorough. Fortunately, the parents were reasonable and sensible, and they realised that eight months' inaction was only to be counterbalanced by a much longer period of patient, continuous effort. In a week from the primary

Hosted by Google

operation I commenced Faradaisation, continuing it on alternate days, in addition to the free movements; the aim was to develop the remains of the injured external rotators with other muscles which might be compensatory and to improve innervation. I picked out the deltoid in particular, the trapezius, rhomboids, &c., also the triceps; and to counteract the constant tendency of the forearm to pronation I tried to increase the development of the supinators longus and brevis, and by inducing strong contractions of the biceps with the forearm flexed to improve its action as a supinator; the radial extensors of the carpus, longior and brevior, were also treated. Rapid increase in the size of all these muscles, with quickened response to stimulus, gave encouragement, and very soon operations were extended with the small button electrode to the small muscles of the undersized thumb, index, and middle fingers, and to the palmar surface of their tips to improve tactile sensibility, with palpable benefit. Sometimes one pole was placed over a muscle and the other over the brachial plexus in the posterior triangle or over the individual nerve supply, and sometimes both poles were placed over either end of one of the longer arm muscles. Frequent intermissions were given to avoid overtiring a muscle. After a month other factors equally as effectual and important helped in the improvement. Nearly all day now the child had his good arm enveloped by a towel tied round his body; he also had a thick stall on the little and ring fingers of the other hand to prevent his customary exclusive use of them. His mother's devotion to a set purpose and her intelligent supervision were now invaluable; she daily gave all her spare time to the various amusements and devices we designed to teach the child external rotation, abduction, supination, and the use of his unaccustomed fingers; it became quite a matter of habit with all the family to discourage the tendency of the limb to internal rotation and pronation; the happy disposition of the child helped us greatly. At the end of two months there was such evident improvement in every way that our task daily grew in interest and lost all tediousness; we began to cultivate the deficient finer movements and sense of touch in the underdeveloped left thumb, index, and middle fingers; with the finger-stall over the other two he was attracted to hold and pick up things. At first he was so awkward and feeble that it was a most difficult matter to get him to take up large lumps of sugar and drop them into a basin, but before many weeks he could confidently pick up such difficult things as pills, small buttons, and safety-pins, coins, &c., with forefinger and thumb opposed in a strong and natural grasp. With his sound arm tied up he now played for hours daily with a variety of articles and with vastly improved method; he was also regularly enticed to reach out after things put round him in different positions, to lift up and take things down from places above him. At the end of four months the regular Faradaisation and free movements—which were now quite painless and easy—with the persistent education of the limb, had effected improvement beyond our hopes. The humerus was very slightly shorter on the one side, but comparison revealed no differences in the muscles now. Force of habit and larger development of the internal rotators always had a tendency to reassert themselves, but the child was now rapidly learning to counteract them by the better use of his improved external rotatory mechanism, which would, however, probably be always weak. At the end of five months we thought our results interesting enough for Mr. Pearce Gould to see, and by his desire the child, now thirteen months old, was taken up to the Middlesex Hospital and shown to his class. It was an interesting case for his hearers, and gave him an object lesson to impress on them that the Schultze method of artificial respiration requires all possible gentleness. Subsequently the little patient went to Germany for a few months. Faradaisation was now almost superfluous, but a battery was taken for occasional use, which the parents could competently manage themselves.

The child was taken recently to see the famous German surgeon, Professor Kraske of Freiburg. I gave him a brief history from the commencement and a statement of the treatment; he has sent me a letter written by a colleague at his request from which the following is an extract. "Besides symptoms pointing to what we call 'Erb's paralysis'—lesion of the fifth and sixth cervical roots above the clavicle—Professor Kraske found the growth of the left humerus impaired, which he was inclined to attribute to traumatic lesion of the upper epiphysis. As to the ultimate result of treatment, Professor Kraske did not feel entitled to express any definite opinion. Since the nervous disturbance had gradually been giving way he considered further improvement very probable." Professor Kraske also says he advised the application of a bandage, which will, while it is worn, fix the humerus in a normal position and prevent its inward rotation. Seven months of treatment had so altered the condition of affairs when Professor Kraske saw the child that it was very difficult for him to realise fully the nature of the primary lesion and the true characters of the resulting deformity. Interesting as his views were, his prognosis was of far more practical importance, and was fully justified, for I now hear that since the intermittent use of Professor Kraske's bandage improvement has been even more rapid than before.

Although I anticipate ultimate success in extent greatly beyond what has been attained, I think the treatment has gone far enough and been successful enough to make the case instructive and to point the moral that in cases of this nature one need not despair of improvement; in fact, in an apparently hopeless instance the commencement of treatment may justify a prognosis which amply repays us for the experiment and encourages us to persevere.

Brighton.

A CASE OF RUPTURE OF THE LIVER SUCCESSFULLY TREATED BY ABDOMINAL SECTION.

BY CHRISTOPHER MARTIN, M.B. EDIN., F.R.C.S. ENG.,
SURGEON TO THE BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.

IN the early part of the afternoon of May 4th, 1896, a strong, healthy young coal miner, aged nineteen years, was caught, whilst down in the pit, between two sets of trucks and received a severe "rolling crush." He was carried to the surface and sent home in a cart, and Mr. J. M. McCarthy, of St. George's, Salop, was sent for. When he saw him, about 4 P.M., the patient had recovered from the first shock. He complained of great pain in the right side of the chest. There were signs of bruising both on the front and back of the chest, especially on the right side. His pulse was 76, his temperature 98° F., and there was nothing then in his general condition to point to any grave internal injury. In the evening he seemed to be better, and he slept during the night till 5 A.M. Next morning (the 5th) he was, however, decidedly worse, and as the day wore on well-marked symptoms of grave abdominal mischief supervened. The pulse became more and more rapid, the temperature steadily went up, the abdomen became distended, the face pinched, and the respiration sighing. Mr. McCarthy wired for me to go over at once prepared to operate. In his telegram he said: "Case of traumatic peritonitis; probably ruptured viscus." When I saw the patient, about 9 P.M., his temperature was 103°, his pulse 130, his breathing short and distressed, his face pinched, and the abdomen was hard, tense, and distended—tympanitic in front, dull at the flanks, and evidently containing much free fluid. There were, however, no signs of free gas in the peritoneal cavity—no obliteration of the liver dulness—showing that the stomach and intestine had probably escaped. There was no vomiting either of blood or bile, no hæmoptysis, and no hæmaturia. He had passed flatus and the urine was clear. The symptoms were those of progressive intra-peritoneal hæmorrhage and advancing peritonitis. These symptoms, the absence of signs of injury to the lungs, stomach, intestines, kidney, and bladder, and a consideration of the mechanism of the crush, led us to diagnose a rupture of the liver. Mr. McCarthy agreed with me that the patient's only chance lay in immediate abdominal section. To this the patient readily consented; but his parents gave way most reluctantly. The operation was done under difficulties, by the uncertain light of a paraffin lamp, in a miner's cottage, in a pit village on a Shropshire hill-side. About 9.30 P.M. Mr. H. H. Rubra put the patient under chloroform, and, with Mr. McCarthy's able assistance, I opened the abdomen in the middle line by an incision reaching from the ensiform cartilage to the umbilicus. As soon as the peritoneum was opened an immense quantity of black blood—fluid and clotted—escaped, and on examination, the liver was found to be ruptured. A rent, from one to two inches deep, ran from before

Hosted by Google

backwards on the under surface of the right lobe, from the portal fissure to as far up the posterior surface as I could reach. There were, in addition, evident signs of commencing peritonitis. I now endeavoured to clear the abdomen of blood-clot by free irrigation with hot water. Floating amongst the clots I noticed a fragment of liver substance wholly detached from the organ. This was examined microscopically by Professor Allen of Mason College, Birmingham, and it proved to be normal human liver tissue. I lay some stress on this fragment, as it is proof positive not only that the blood came from a rent in the liver, but also that the lesion of the liver must have been a severe one. Probably there were other small fragments detached, but they escaped notice amongst the clots. The question then was how to deal with the rent. Had it been on the anterior border or upper surface I could have sutured it with catgut or plugged it with iodoform gauze; but it extended so far backwards and upwards on the posterior surface that suturing was impossible, and I considered that gauze plugging was impracticable. I decided to trust to the hæmostatic effect of free irrigation with hot water, thorough removal of all effused blood from the peritoneal cavity, and free drainage. I accordingly again washed and sponged out the abdomen. In order to effectually drain the pelvic pouch I made a short incision just above the pubes. I then inserted two glass drainage-tubes—one through the epigastric incision going down to the rent in the liver, and the other through the suprapubic opening into the pelvis. The parietal wounds were closed with silkworm-gut sutures, antiseptic dressings were applied, and the patient was lifted back to bed. It was fortunate that I made the suprapubic opening, as for several hours there was a free bloody discharge from the lower tube, though practically nothing came through the upper tube. The patient stood the operation well, but a condition of grave abdominal collapse continued during most of the following day. His temperature fell markedly after the operation, but his pulse continued from 130 to 140 and was at times intermittent and uncountable. Thanks, however, to the frequent administration of brandy and beef-tea enemata, small quantities of brandy by the mouth, and small doses of morphia hypodermically, the patient rallied, and during the afternoon (May 6th) had four hours sleep. Mr. McCarthy and his assistant (Mr. Rubra) were most assiduous in their attention, and the patient owes his recovery in a large measure to their careful after-treatment of the case. After the first twelve hours there was very little bloody discharge from the drainage-tubes, and what there was came from the lower tube. That from the upper tube was scanty, serous, and for a few days bile-stained. On the 10th the glass tubes were removed and rubber tubes inserted. These were gradually shortened from day to day. On the 11th, although his abdominal condition was most satisfactory, the patient developed symptoms of pneumonia. For several days he brought up semi-purulent blood-stained sputum, had a moderate degree of fever, a troublesome cough, and quick, distressed breathing. On the 20th his temperature fell to normal, and from that date he progressed rapidly to recovery. The patient is now (April, 1897) fat, strong, and hearty.

Remarks.—Rupture of the liver, though by no means a rare accident, is a terribly fatal one. The chief causes of death are shock, hæmorrhage, and peritonitis: (*a*) shock from the bruising, tearing, and pulping of a vital organ; (*b*) hæmorrhage from the laceration of the great vessels at the portal fissure and traversing the liver substance; and (*c*) peritonitis from secondary septic changes in the extravasated blood and bile. At the same time it is not an absolutely mortal injury. There have been several instances in which, from the nature of the accident, the clinical signs and symptoms and the after progress of the case, it is extremely probable that the liver was ruptured, and yet the patient recovered. Still more conclusive are four cases (published by Heath, Erichsen, Morris, and Hammond) where the patients survived the accident—14, 16, 21, and 38 days—and then died from other causes. In each case a post-mortem examination showed that the liver had been ruptured—more or less severely—and that a spontaneous cure was taking place. Such cases, however, form an extremely small minority. In the vast majority—probably 99 per cent.—death rapidly takes place. In the above case I am convinced that had the patient not been operated on he would certainly have died. After the first shock of the accident passed off he had no bad symptoms for sixteen hours, during which time he had several hours' sleep. Then he began to show signs of progressive intra-peritoneal hæmorrhage and advancing peritonitis. Hour by hour his condition became graver, and when I saw him some thirty hours after the accident it was evident that he was doomed—unless we could save him by abdominal section. But how did the operation save him? I attribute the good result to the free irrigation of the peritoneal cavity with hot water and to the thorough drainage. By the irrigation I checked the bleeding from the rent in the liver, and removed a vast quantity of effused blood and lymph from the peritoneum. The drainage tube—properly used—is itself an excellent hæmostatic, as all who have had much experience of pelvic surgery are well aware. By draining away the blood as soon as it was poured out it promoted the natural arrest of hæmorrhage. Furthermore, the removal of the effused blood, lymph, and bile checked the progress of peritonitis and prevented its further development. I lay stress on the importance of draining the pelvic pouch by an opening just above the pubes. It is significant that most of the discharge came through the pelvic drainage-tube. In conclusion, I trust that the successful issue of this case will encourage other surgeons to try to save, by timely operation, cases in which the same terrible accident has occurred.

GUY'S HOSPITAL.

EXTENSIVE MALIGNANT DISEASE OF THE TONGUE AND FAUCES; REMOVAL; RECOVERY.

(Under the care of Mr. J. N. C. DAVIES-COLLEY.)

THE very great extent of the structures in the mouth involved in the following case necessitated a departure from the usual Whitehead operation, and the buccal incision, which is generally associated with the name of Furneaux Jordan, though previously described by F. J. Gant, exposed the affected parts better than any other of the numerous incisions which have been employed for removal of the tongue. The approximation of the edges of the mucous membrane and the use of an antiseptic locally account in great part for the rapid healing. As to the prognosis nothing can be said; but whether the disease returns or not the patient is much the better for the removal of so extensive a malignant ulcer. For the notes of the case we are indebted to Mr. H. W. Dudgeon, clinical assistant.

A man, aged fifty-six years, was admitted into Guy's Hospital on March 24th, 1897, complaining of disease of the tongue. He had first noticed a pimple far back on the right side of the tongue just after Christmas, 1896. Thinking it was due to chewing tobacco he gave up the practice, but the pimple steadily grew larger, and continued growing up to the time of the patient's presenting himself at the hospital. For the last seven weeks before admission he had not been able to swallow solid food, and consequently his diet had been entirely fluid. Six days before admission he had, he said, vomited about two quarts of liquid blood with a small mass of solid blood clot. He had never had any pain in the tongue, throat, or stomach except the pain caused by attempting to swallow solid food. For some weeks an offensive purulent discharge had run from the mouth. He had, he thought, lost a good deal of flesh in the last few months, but he attributed it to the abstinence from solid food. On admission the patient was seen to be a well-formed man, but thin. On the right side of the tongue were two extensive ulcers situated for the most part on the posterior half of the tongue. The edges were raised and everted and the centres deeply excavated; the bases were very hard, and the hardness extended downwards into the floor of the mouth on the right side, backwards to within half an inch of the epiglottis, and upwards to the right tonsil and the right half of the soft

Hosted by Google

palate. On attempting to swallow he was unable to raise the tongue from the floor of the mouth, to which it had become firmly adherent. The tongue could be protruded slightly, and it then deviated markedly to the right. No enlarged glands could be felt either under the jaw or in the neck, but there seemed to be a fulness beneath the right angle of the jaw. He complained of no pain in the mouth except when taking food, but occasionally he experienced a sharp pain in the right ear. The other organs of the body were healthy. On March 26th the patient was anæsthetised, at first with the A.C.E. mixture and subsequently with chloroform by means of a Junker's inhaler. A gag was introduced on the left side by which the mouth was forcibly opened, and the tongue was transfixed near its apex by a stout silk ligature, by which it was drawn as far out of the mouth as possible. By means of a scalpel the right cheek was cut through in a line with the mouth as far back as the wisdom tooth. Mr. Davies-Colley then snipped away with the scissors all the affected part of the gum, the anterior pillar of the fauces, the right tonsil and part of the soft palate, and finally, by a somewhat oblique incision, practically the whole of the tongue was removed. There was very little bleeding. The cut edges of the mucous membrane were approximated by salmon-gut sutures and the margins of the incision through the cheek were joined by means of a button suture. The patient bore the operation well. A mouth-wash of a solution of resorcin, ten grains to the ounce, with a drachm of glycerine, was used. He was fed by nutrient enemata, and also took a little milk by the mouth. His recovery from the operation was rapid and uneventful, and on April 1st the button suture was removed. At no time after the operation did he complain of any pain, and at an early date he took all his nourishment by the mouth. On April 12th he was practically well.

Remarks by Mr. DAVIES-COLLEY.—This case of epithelioma of the tongue is interesting on account of the great extent of that organ as well as of the soft palate and right tonsil involved without any perceptible enlargement of the lymphatics. I thought, therefore, that I was justified in removing the disease through the mouth by Whitehead's operation. I did not find it necessary to perform laryngotomy, and very little blood got into the air passages, although the section of the dorsum of the tongue on the right side came near to the epiglottis.

GREAT YARMOUTH HOSPITAL.

A CASE OF VERY EXTENSIVE FRACTURE OF THE BASE OF THE SKULL; NECROPSY.

(Under the care of Dr. H. BLAKE.)

THE extensive fracture of the base of the skull which was found post mortem in this case is somewhat unusual from a blow on the occiput. A circular fracture of the base surrounding the foramen magnum is by no means rare when resulting from a fall on the vertex, for then the occipital condyles and the adjacent portions of bone are driven into the skull by the momentum of the body acting through the cervical vertebræ. The ecchymoses seen over the mastoid processes are recognised as a trustworthy sign of fracture of the posterior fossa. For the notes of this case we are indebted to Dr. K. W. Monsarrat, house surgeon.

A man, aged fifty years, was admitted to the Great Yarmouth Hospital on June 2nd, 1896, with a history of having received a blow on the back of the head by a fall which brought it in contact with the kerbstone. He was intoxicated at the time. When admitted he was unconscious, the breathing was stertorous, and there was free hæmorrhage from both ears. The pupils were contracted and equal, both reacting to light; there was a slight conjunctival reflex. Over the occipital bone on a level with the protuberance, and rather more to the left than the right of the middle line, was a large bruise, but there was no other mark of external violence. On the night of the 2nd he developed a condition of great irritability and restlessness, so that he had to be tied down in bed. The struggling was noticed to be much more marked on the right side of the body than on the left. He continued in this state until he died, except that on half a dozen occasions, all at night, he asked rational questions as to why he was tied down, &c.; as a general rule, however, he lay struggling and muttering. On the night of the 7th he had two general convulsions without any localising symptoms. At midnight on the 8th he died.

Necropsy.—The post-mortem examination was made seventeen hours after death, and the following are the notes of interest. There was a distinct flattening of the skull about the region of the external occipital protuberance over an area three inches in diameter; there was no ecchymosis there, but behind each ear over the mastoid there was a distinct bruise. On removing the skull-cap there was found an extensive sub-dural hæmorrhage over the left parietal region, without appreciable flattening of the convolutions. There were also small punctiform hæmorrhages over the right occipital and parietal and the left occipital areas of the cortex. Both frontal lobes were lacerated at their anterior extremities, and there was a considerable amount of clot in their torn substance, especially on the left side; there was also a large clot in the substance of the anterior extremity of the left temporo-sphenoidal lobe and in the central part of the left middle temporo-sphenoidal convolution. On removing the brain there was seen to be a fracture commencing at the torcular Herophili and extending outwards on each side to the junction of the petrous and squamous portions of the temporal. Each petrous bone was fractured in several directions, and the line thence extended to meet its fellow of the opposite side on the sella turcica, the posterior clinoid processes being chipped off and loose. The line of fracture was thus completed round the foramen magnum, and was fourteen inches in extent. The skull was of the usual density and thickness.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Lymphadenomatosis of the Bones.—Dermatitis Maligna.—Bodies in the Vermiform Appendix.—Rupture of the Heart.—Mucosal Cysts.—Gumma of the Spleen.

A MEETING of this society was held on May 4th, the President, Mr. BUTLIN, being in the chair.

Dr. F. PARKES WEBER showed specimens of General Lymphadenomatosis of the Bones from a man aged sixty-one years. He complained of pains in different parts of the body, and notably of bilateral abdominal pains, usually worse when he stood up. His spinal column was kept rigidly fixed; there was kyphosis, which appeared to be progressive; and he walked slowly and carefully with the aid of a stick. A little variable œdema over part of the spinal column and one lower extremity was noticed. His appetite was good and he had no fever, yet he became gradually weaker, and looked more like a man of eighty than one of sixty-one years. His actual death resulted from an asthenic type of pneumonia in both lungs. At the necropsy all the bones which were examined (including all the vertebræ and ribs, the clavicles, and the calvarium) were found more or less affected with the disease. A very vascular, small round-celled growth occupied the centre of the bones and partially replaced the osseous tissue. In some localities the growth was only covered by periosteum, all the osseous tissue beneath it having been absorbed. Portions of the ribs were bulged owing to distension by the rapidly growing neoplasm in their interior. There were some enlarged lymph glands under the right clavicle; these were apparently the site of a similar, but less vascular, growth. The kidneys showed a moderate amount of interstitial change, and in two white specks below the capsule minute, concentrically marked calculi could be seen with the microscope. These, Mr. Shattock ascertained, consisted of phosphates. The lungs showed greyish consolidation at both bases. Part of the consolidated lung was examined microscopically and presented a peculiar homogeneous hyaline appearance of the material between the cells. Unfortunately in the present case no examination of the blood was made. Dr. Weber thought that his case was of the same nature as those variously described as "multiple myeloma," "medullary pseudo-leukæmia," "myelogenic leukæmia," "pernicious anæmia with associated affection of bone marrow," and "primary sarcomatous osteitis."—The PRESIDENT said that in a case which he exhibited before the society in 1879 there were definite myeloid tumours. The existence of any disease had not been suspected until the

Hosted by Google

occurrence of a fracture of the femur shortly before death. At the necropsy it was found that the affection of bones was a widespread one. There were other cases on record in which there was nothing during life to suggest the existence of the disease.—Mr. W. G. SPENCER said that when fresh the bones in this case, and in others which he had observed, had a peculiar raspberry-red colour. The colour quickly faded when the specimens were placed in hardening solutions.

Dr. ROLLESTON and Mr. E. L. HUNT brought forward two cases of Dermatitis Maligna, or Paget's Disease of the Skin, in both of which carcinoma subsequently developed. The first case was that of a man, aged sixty years, who had had the glazed, raw condition of the skin above the pubes characteristic of the disease for eight years; two years ago nodules of carcinoma developed. The whole affected area was removed and the man recovered. A somewhat similar case, in which the scrotum and penis were affected, had been described by Dr. Radcliffe Crocker. The carcinoma probably developed from the sebaceous glands, and not from the superficial layers of the skin. The sweat glands were dilated, but did not, as in Dr. Crocker's case, appear to be undergoing carcinomatous change. The growth was a spheroidal-celled carcinoma. The second case was that of a woman, aged forty-five years. The skin affection began eight years ago on the sinus of a mammary abscess, and had spread most extensively. A year ago carcinoma developed. The whole affected area, together with glands from the axilla, was successfully removed. Microscopically the carcinoma appeared to be squamous-celled, showing a transition to a spheroidal-celled type, but no keratinisation had taken place. The modification was probably due to the extensive inflammatory changes, which were also thought to be responsible for the extensive vacuolation seen in the epithelial cells. The carcinomatous growth had certainly not arisen in the mammary glands or in the ducts, as was often the case. It was suggested that Sir James Paget's name would best be honoured by associating it with the actual morbid lesion, a long-standing dermatitis of the nipple, which he originally described, and not with analogous lesions. Both these cases had been most kindly placed at the disposal of Dr. Rolleston and Mr. Hunt by Mr. Marmaduke Sheild.—Dr. THIN said that he had seen one of the cases during life and had made sections from the parts removed. He dissented from the view that the changes were the same as those met with in rodent ulcer. The cells in rodent ulcer had very little protoplasm round the nuclei, while in Dr. Rolleston's specimens it was abundant, the cells being of the same character as those met with in ordinary epithelioma. He was sceptical as to whether carcinoma ever arose from the sebaceous glands, and could see no evidence of it in this case.—Mr. SPENCER did not think the name given to these cases quite a happy one. At the time of death there was no dermatitis, and the term "maligna" was ambiguous because it was often applied in the sense of "virulent" as well as to denote new growth. He thought that the cases came under the category of rodent ulcer and represented two somewhat divergent types, the squamous form, as in Dr. Rolleston's second case, and a commoner sebaceous form, illustrated by the first case.—Dr. ROLLESTON, in reply, said that the term "dermatitis maligna" was given to the cases by Dr. Thin soon after Sir James Paget had described his cases of disease of the nipple. In one of his cases there was dermatitis for seven years before any sign of malignant disease declared itself.

Dr. ARTHUR LATHAM showed a Vermiform Appendix which had been removed from a man, aged forty-six years, who had died from lobar pneumonia. There was no history of any symptoms connected with the appendix having occurred during life. The specimen was nine centimetres long and considerably dilated throughout its course. There was no communication between the appendix and the cæcum, the lumen of the former having been obliterated at its junction with the cæcum by adhesive enteritis. The appendix was completely filled with numerous small bodies which had the appearance of ova. The larger of these was of about the size of a dried pea. On microscopical section they showed an irregular fibrinous structure, which in places was somewhat laminated. They did not give a mucin reaction and stained readily with acid dyes. The wall of the appendix was irregularly honeycombed owing to pressure exerted by the above bodies. It was further thickened, and on section showed loss of mucous membrane and also of lymphoid tissue, possibly due to membranous enteritis. He had been unable to find any similar case recorded.

Dr. HINGSTON FOX showed a specimen of Non-perforating Rupture of the Heart, taken from the body of a stout woman, aged sixty-nine years, of good health and active habits. She was seized with præcordial pain after fatigue and a cold bath; nitrite of amyl was useless, but morphine hypodermically and a small venesection partially relieved her, and she lived forty-eight hours, troubled with vomiting and pyrexia (to 100·5° F.). Death was sudden, on slight movement. At the necropsy the pericardium was found to be full of blood; the heart, weighing fourteen ounces, was loaded with fat; and two small, superficial rents were seen on the wall of the left ventricle, not perforating the wall, and a small ecchymosis beneath the visceral pericardium at another spot. It was probable that during exertion the distended, fatty heart had ruptured the exocardium and some muscular fibres at these sites, causing slow leakage of blood, and death two days later, apparently from syncope. This form of rupture, non-perforating and but slowly fatal, from hæmorrhage appeared to be extremely rare.

Mr. S. G. SHATTOCK made a communication on Mucosal Cysts and on the significance of the Stratum Granulosum. He described three cysts removed from the neck. One, from the upper part of the neck, was lined by stratified squamous epithelium, another by columnar epithelium, whilst in the third both forms were present at different parts of the cyst. He wished specially to draw attention to the absence of any stratum granulosum. He should call all "dermoid" cysts in which no stratum granulosum could be detected "mucosal" cysts, differing from Mr. Bland Sutton, who classed all cysts, whether lined by mucous membrane or skin, as dermoids, on the ground that no line of demarcation could be drawn between skin and mucous membrane. He thought that the presence or absence of this stratum was sufficient to decide which was present. Mucous cysts, due to retention in a mucous gland, must, of course, not be confused with these mucosal cysts. Mr. Shattock remarked that the best way of demonstrating the granules histologically was by staining the sections by Gram's bacteriological method. In true dermoid cysts Mr. Shattock had never failed to find a stratum granulosum, and this was equally true of such dermoids as were devoid of epidermal appendages. He had examined three of this nature from the limbs, and one from the right lumbar region, which arose at the site of a bullet injury. Mr. Shattock held that no appendages were developed in implantation cysts, such hairs and glands as did occur being there by direct implantation only. In the epidermal covering of scars, both in animals and in plants, no growth of hairs or glands ever occurred. The granular cells were not found in the sebaceous glands, but they were found throughout the whole length of the hair follicle, and hence in sebaceous cysts, which really arose in the hair follicle, a stratum granulosum was to be found.

Dr. G. F. STILL showed two specimens of Gumma of the Spleen occurring in the subjects of Congenital Syphilis. The first was that of a boy, eleven years of age, who was under the care of Dr. Lees at the Hospital for Sick Children, Great Ormond-street, suffering from anæmia and an enlarged spleen and a general enlargement of the lymphatic glands, supposed to be due to lymphadenoma. After death the spleen was found to be greatly enlarged and to contain thick fibrous cicatrices in its substance. It was extensively affected with lardaceous disease, and the splenic vessels showed peri- and end-arteritis. There was cirrhosis of the liver of the kind usually met with as a result of congenital syphilis, and there was general enlargement of the glands, which were almost completely converted into fibrous tissue and showed syphilitic changes in the vessels. There was a record of a similar case in which the gummata were small and multiple occurring in the hospital some years ago.

Dr. STILL also showed a specimen from the museum of the same hospital taken from a child, eleven months old, who was under the care of Dr. Barlow some years ago, suffering from well-marked congenital syphilis and an enlarged spleen. There was a localised patch of fibrous tissue in the capsule about one-third of an inch in thickness, which was probably a gumma, although direct evidence, such as the existence of endarteritis in the neighbourhood, was wanting. Gumma of the spleen even in adults was very uncommon, and he had only been able to discover four other cases recorded, all by German pathologists, of its occurrence in children. In almost all there were gummata of the other organs, and in half the cases the gummata were miliary in size.

Hosted by Google

Mr. P. FURNIVALL reported that he had made a further examination of a specimen exhibited to the society in November, 1896,[1] by Dr. Kanthack and himself as a case of Myxo-sarcoma of the Colon, and they had now no doubt that it was a specimen of colloid carcinoma. The boy was only fifteen years of age when the growth was noticed, and in several recorded cases the growth had manifested itself at an unusually early age for carcinoma.

HARVEIAN SOCIETY OF LONDON.

The Anæsthetisation of Children.

A MEETING of this society was held on April 29th, Dr. MILSON being in the chair.

Mr. GEORGE ROWELL read a paper on the Anæsthetisation of Children, which will appear in our columns. The method advocated was to begin with the A.C.E. mixture and continue with ether.

Dr. FREDERIC HEWITT said that the guide suggested for estimating the depth of ether anæsthesia in children was a very valuable one. With regard to the vomiting, he considered that an interval of four or five hours after food was sufficient to avert vomiting under nitrous oxide and oxygen, and the anæsthesia thus obtained was the safest yet discovered. The tranquil breathing and somewhat equivocal signs displayed by some children under chloroform constituted an objection to this anæsthetic. He had found that in such cases when employing chloroform it was a good plan when in doubt to press the lower jaw back and so produce snoring-breathing. The slight obstruction caused more vigorous and deeper breathing and better anæsthesia also. He strongly supported Mr. Rowell in his preference for ether in the case of children, but he thought that if ether were not well borne in any case or if any embarrassed breathing arose it was a good plan to continue with chloroform. The latter given just after ether produced effects quite unlike those seen when it was used from the first, and a comparatively light anæsthesia was possible and advantageous. Mr. Rowell had said but little on the subject of laryngeal stridor in children. He (Dr. Hewitt) thought it an important matter. Some years ago he was in the habit of attempting to overcome it by producing a deeper anæsthesia; but he now found that it was better to withhold the anæsthetic until the stridor had subsided. He was aware of the remarkable effects of the particular succession of anæsthetics to which Mr. Rowell had alluded, and, in fact, he had several years ago drawn attention to this point.

Dr. SILK, as a visitor, fully endorsed the view that chloroform was by no means so safe with children as was generally supposed; in fact, he thought that many more fatalities occurred from its use than were actually recorded, and that dangerous symptoms were even more apt to develop in children than in adults. Personally, he preferred the A.C.E. mixture for routine use with children. He had been aware of the principle of giving ether by the semi-open method consecutive to A.C.E. for some time, and had frequently employed it in practice, but he had not worked out the details of the plan so carefully as had Mr. Rowell.

Dr. COCK said that he had used the open method of ether administration after beginning with the A.C.E. mixture occasionally, but it was in a good many cases possible to put quite young children under the influence of ether alone from the beginning, and that without much trouble or the usual drawbacks of ether administration in the very young. Some infants would take this anæsthetic as comfortably as chloroform, using a very fine nozzled drop bottle (Esmarch's) and the German pattern of Skinner's inhaler covered with stockingette and not with flannel.

Mr. ROWELL, in reply, said that laryngeal stridor under ether tended to right itself and was of different significance from the same symptom under chloroform.

HUNTERIAN SOCIETY.

Cerebellar Disease.—Headaches.

AN ordinary meeting of this society was held at the London Institution on April 28th, Dr. G. E. HERMAN, the President, being in the chair.

Dr. ARTHUR DAVIES exhibited a case in which there had been apparent symptoms of Cerebellar Disease, from which the patient had entirely recovered.

[1] Vide THE LANCET, Nov. 21st, 1896, p. 1468.

Dr. HINGSTON FOX introduced a discussion on Headaches by a paper which will shortly appear in our columns.—Dr. HAIG agreed as to the relationship between plus tension and headache, and gave an account of the *rôle* of uric acid in producing headache, and pointed out how by eliminating uric acid and the xanthin group in diet, not only was the headache cured, but the blood decimal markedly improved.—Dr. HARRY CAMPBELL inquired as to the exact relationship between headache and plus tension, and whether both might not be due to the same cause. He dwelt on the difficulty of ascertaining the degree of tension, and considered the aortic second sound as often very misleading, and had sometimes found it increased with a low-tension pulse. Cases of migraine with low-tension pulse were common. He regarded headache as a symptom arising from peripheral irritation in the eyes, nose, teeth, scalp, and ears, and intra-ocular tension. The anæmic headache and that common at the menopause and the syphilitic headache were dwelt upon.—Dr. DUNDAS GRANT found nasal disease a cause of a certain number of headaches, especially when the middle turbinated bodies or the sinuses were affected. Cocaine afforded relief in these cases. Localisation of headache was found to be of little value. In the vertical headache of women suffering from leucorrhœa chloride of ammonium was almost a specific.—Dr. GLOVER LYON pointed out the great value of quinine in three-grain doses in the treatment of migraine.—Dr. J. H. SEQUEIRA considered headache as not the result of plus tension, but as being associated with it.—Dr. J. F. WOODS spoke of the treatment of headaches by hypnotism and suggestion.—Dr. HINGSTON FOX replied.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

THIS society held a clinical meeting on March 16th in the out-patient room of the Leeds General Infirmary.

Mr. LITTLEWOOD showed four cases illustrating the treatment of Joint Tuberculosis by Iodoform Injections. The first patient was a female, aged thirty years, who suffered from tuberculous disease of the elbow-joint, with a history of four years' duration. She was admitted to the Leeds Infirmary on Feb. 11th, 1896, and there was then extensive tuberculous disease of the left elbow-joint, with five sinuses leading down to the soft carious bone. There was also an enlarged gland the size of a walnut in the middle of the arm, and the axilla was full of enlarged glands. The first injection was given on Feb. 12th, 1896, and was followed by twenty-three others, the last being given on Aug. 6th, 1896. She was only in the infirmary for three days and was then treated in the out-patient room. The sinuses have all healed, the enlarged glands can scarcely be felt, and she is now using her arm with great comfort, although there is some limitation of movement. The second patient was a boy, aged eight years, suffering from tuberculous disease of the hip, the history being that he had a fall four and a half years ago and had been lame since then. About Easter in 1896 he again had a fall and his condition became much worse. He was admitted to the infirmary on Sept. 1st, 1896, having well-marked signs of right hip-joint disease with abscess. The subsequent progress of the case was as follows. On Sept. 4th, 11th, 25th, and Oct. 8th the patient was aspirated, two ounces of pus being removed the first time and one and a half ounces on the other three dates. Iodoform was injected on each occasion. On Oct. 25th some clear fluid was squeezed out through the cannula and the patient was again injected. The hip was again injected on Nov. 16th and 30th. At the present time the boy is running about without a splint. The third patient was a man, aged thirty-two years, who suffered from tuberculous disease of the right shoulder-joint. He was first seen by Mr. Littlewood in August, 1896. The joint was then swollen and fixed, and any attempt at movement was extremely painful; there was a sinus in front, just above the insertion of the deltoid. The disease in the joint commenced two years ago, and seven weeks previously to this he had an attack of pleurisy. The joint commenced to discharge from the sinus in August, 1895. He had been injected ten times with glycerine and iodoform. He had had no pain since the first injection and had gained one stone in weight. During this time he had been taking petroleum emulsion. The fourth patient was a female, aged nineteen years, who suffered from tuberculous disease of the ankle joint, which

Hosted by Google

commenced twenty-one months ago. She was admitted to the infirmary on Oct. 24th, 1896. The right ankle was then much swollen. The swelling extended upwards to beyond the malleoli and downwards to the tarsus. There were three sinuses—one on the outer and one on the inner side and the third behind. All attempts at movement caused considerable pain. The first injection was given on Oct 26th and after it ten others. She came to the infirmary about once a fortnight, and then went home the day after the injection with the leg in plaster. Both the local condition and her general health have greatly improved.

Mr. LITTLEWOOD also showed a case of Diffuse Popliteal Aneurysm treated by Excision. The patient was a man, aged thirty-seven years, who was admitted to the infirmary on Feb. 8th, 1897, with a large diffuse popliteal aneurysm. He first noticed some stiffness in the ham six weeks previously. After this the swelling increased rapidly and there was a good deal of pain. On Feb. 17th all clot was turned out, and the aneurysmal portion of the vessel was excised. There was no pain after the operation. The wound healed rapidly. The man left the infirmary on March 16th, and he now walks about quite comfortably.

Mr. LITTLEWOOD also showed a small Calculus removed by Nephro-lithotomy from a man, aged twenty-seven years, who had had attacks of renal colic on the left side for four years. Twelve months ago for one day he passed some blood, but he never passed any calculi. An incision was made in the kidney at the lower end, and a small calculus weighing two grains was removed. The wound was quite healed and the stitches removed on the fifteenth day afterwards.

Mr. LITTLEWOOD also described a case in which a Sarcoma of the Upper Jaw was removed three and a half years ago. The patient was a man, aged fifty-six years, who was admitted to the infirmary on Oct. 2nd, 1893, with a sarcoma involving the superior maxilla and malar bones in the left side. He first noticed the swelling two months previously. On Oct. 4th, after preliminary laryngotomy, the upper jaw was removed with the malar bone and part of the zygoma. There has been no recurrence since.

Mr. LITTLEWOOD also showed a patient whose right kidney was removed six years ago for Tuberculous Disease.

Dr. WARDROP GRIFFITH showed a boy, aged sixteen years, who presented the phenomena of well-marked Unilateral Convulsions, which always began in the left hand, sometimes spread to the face and leg, and sometimes culminated in unconsciousness. There was no optic neuritis and no definite signs of gross intracranial disease.

Dr. GRIFFITH also showed a child, aged five years, with symptoms indicative of a Lesion in the Right Side of the Pons involving the Nucleus of the Sixth and partially that of the Seventh Nerve. There was complete paralysis of the right external rectus with partial paralysis of the right side of the face of Bell's type. There was no optic neuritis.

The following cases were also shown:—

Dr. MOUILLOT: A case of Raynaud's Disease in which the hands and feet were markedly affected.

Dr. CHURTON: A case of Traumatic Paralysis of the Left Hand with Sensory, Vaso-motor, and Trophic Symptoms.

Dr. TREVELYAN: Three cases of Graves's Disease and an unusual case of Laryngeal Tuberculosis.

Dr. BARRS: (1) Thoracic Aneurysm with Laryngeal Palsy; and (2) Enlargement of the Spleen with Hæmatemesis.

Dr. WELLS: An Unusual Form of Muscular Dislocation.

Dr. BRONNER: (1) Three cases of Senile Cataract operated on without Iridectomy; and (2) cases of Radical Cure of Mastoid Disease.

Mr. H. SECKER WALKER: (1) A case of Radical Cure of Mastoid Disease; and (2) cases of Mules's Operation.

Mr. W. H. BROWN: (1) A case of Gastro Enterostomy; (2) Malformation after Burns; and (3) Primary Syphilis in a Child.

Mr. WARD: Resection for Ununited Fracture.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

The Diarrhœas of Children.

A MEETING of this section was held on April 9th, Dr. G. F. DUFFEY, President, being in the chair.

Mr. LANGFORD SYMES read a paper entitled, Some Introductory Remarks on the Diarrhœas of Children, in which reference was made to the enormous mortality amongst children from diarrhœa, the difference in the digestive juices in the child as compared with adults, the digestion of milk by infants in the intestine, and the inability of young children to digest starch. Defective water-supply appears to affect principally children over five years of age, but infants are swept away in hundreds by milk which is infected or contaminated. The greater number of fatal diarrhœas are doubtless due to artificial feeding. In Manchester, according to Dr. Niven's returns, 97 per cent. appear to have been hand-fed. This identical percentage was also found to be the rule in America, and Bavaria returned 96 per cent. Mr. Symes classified diarrhœas as (1) dyspeptic, including simple diarrhœa and chronic diarrhœa; and (2) infective, including summer diarrhœa and cholera infantum. Such names as entero-colitis, catarrhal enteritis, muco-enteritis, and gastro-intestinal catarrh are misleading, and cannot be borne out by facts. The prevention of all these diarrhœas can be reduced to three lines of action—scientific regulation of artificial feeding, purification of the ground, and purification of milk.

Dr. W. G. SMITH said that the small intestine was the chief seat of digestive processes in adults as well as in children, and he agreed with Mr. Symes in saying that chemical changes were produced by micro-organisms in the small intestine.

BOMBAY MEDICAL AND PHYSICAL SOCIETY.

Epithelial Xerosis.—Necrosis of the Internal Ear.—Foreign Bodies in the Bladder.—Osteo-mollities.—Radiograph of a Snake.

THE first meeting of this society was held at the Esplanade Hotel Annexe on Feb. 5th, Brigade-Surgeon-Lieutenant-Colonel J. ARNOTT, Vice-President, being in the chair, and twenty-five other members being present.

Surgeon-Captain H. HERBERT read a paper on Epithelial Xerosis in natives of India, illustrating it by patients, photographs, and microscopical sections. He said that the patients showed examples of a general degeneration and chronic inflammation of mucous membranes very commonly met with in Bombay amongst the poorest classes. Very often the conjunctiva, more especially in its exposed strip on either side of the cornea, is the first membrane to show definite changes, and in the milder instances it may be the only one. During the four months from June to September, 1896, Surgeon-Captain Herbert tabulated 100 consecutive cases. Epithelial xerosis of the cornea has been described as a degeneration of the membrane found in debilitated persons exposed to strong glare and in marasmic infants, and showing itself mainly in the formation of dry greasy patches on either side of the cornea. The collection of cast-off epithelial cells and Meibomian secretion which usually covers these areas has been conveniently spoken of as "foam." The conjunctiva is generally thickened, inelastic, and wrinkled, there may be a good deal of inflammatory secretion, and in infants the cornea is liable to rapid suppurative destruction. By far the commonest xerotic area is a small patch just outside the cornea; in 100 cases this spot alone was affected four times as often as the conjunctiva on both sides of the cornea; the inner site was never alone xerotic. The xerotic patches tend to be cast off by inflammation of the cornea, primary and secondary, so that when both corneas suppurate, as they often do, there may be very little beyond a characteristic pigmentation of the conjunctiva to show the true origin and nature of the case. In 16 of the 100 cases there were no xerotic patches whatever, their absence being accounted for by keratomalacia or suppurating ulcers in nearly all. The xerotic degeneration was shown by conjunctival pigmentation, thickening, and wrinkling, and often by finely granular lids. The pigmentation is absent in white-skinned races, so that in them such cases might be difficult of interpretation. In the mild cases the patches are often thinly covered with bright, white, glistening "foam," which is sometimes frothy. Of more interest are the thick collections of soapy material on the lid borders sometimes seen in cases of conjunctivitis, primary or secondary, in Bombay. This material is quite different from the thin, frothy collections on canthi or lid margins seen both in England and India; it is indistinguishable under the microscope from that taken from a xerotic patch, and contains the same bacillus in great numbers—one closely resembling the

Hosted by Google

diphtheria bacillus in its appearance. The next evidence of degeneration described was a dirty or muddy-brown colouration resulting from an excessive development of the pigment normally to be detected in an Indian conjunctiva under the microscope. The depth of the tint depends largely on the complexion of the individual, as well as on the degree of the xerosis and the length of time it has lasted. In the commonest type the pigmentation is fairly general on both the lids and eyeball. There is never much on the upper part of the eye. It is well developed on the exposed conjunctiva on either side of the cornea and on the strip immediately below the cornea; the lower fornix is often the most deeply coloured portion of the whole membrane. This pigmentation is characteristic of xerosis, and must not be mistaken for the effects of malarial cachexia, for malaria does not colour the conjunctiva except by weakening the patient and so predisposing to xerosis. After a time "granulations" are formed, usually limited to the tarsal portion of the upper lid and extremely small. In severe cases the cornea commonly shows opacity and dulness, and it is often ulcerated. Insufficient and improper food and lowered general vitality are the principal causes of conjunctival xerosis; the chief reason for its being mainly a tropical affection is not because the glare of the sun is strong, but because in warm climates the poor can support life in a state of chronic inanition which would be impossible elsewhere. The only treatment which seems to have been serviceable is improving the general health and bandaging the eyes; the bandage, however, is often inapplicable owing to corneal complications.

Surgeon-Major W. K. HATCH described a case of Necrosis of the Internal Ear. No history of the patient's illness could be obtained; she was fairly nourished and apparently about thirty-five years of age; her speech was quite unintelligible and she seemed to hear nothing. The left auditory meatus was blocked by a red granular mass, and the part was extremely painful. Dead bone could be felt with a probe, and by means of a gouge a large sequestrum was removed, consisting of the external auditory meatus, semicircular canal, and cochlea. In the result the place healed completely and the patient was discharged from hospital in a fairly good condition.

Surgeon-Major HATCH then gave an account of the Removal of Three Pieces of "Grass Stick" from the Bladder of a woman with a No. 6 lithotrite and exhibited the Skeleton of a female who was the subject of Osteo-mollities; the whole weight of the bones was—skull 6 oz., other bones 17⅛ oz.

Dr. PECHEY-PHIPSON showed a Radiograph of a Snake in which the solid urinary matter was distinctly seen. This was of interest in connexion with the possibility of diagnosing calculi in the human bladder by this means.

MEMORIAL TO THE LATE MR. JOSEPH FRY.—Lord Hillingdon, the treasurer of the "Joseph Fry Memorial Fund," is making an urgent appeal to all those who have not yet subscribed to the fund to send their contributions to him as soon as possible, to 67, Lombard-street, as the committee are anxious to close the subscription list at an early date. It is proposed to endow a bed at the Metropolitan Hospital and to erect a drinking fountain to his memory.

MEDICAL MEN AND CLUBS.—At Truro County Court, on April 23rd, Mr. W. Whitworth, M.R.C.S. Eng., L.S.A., of St. Agnes, Cornwall, sued a labourer of Goonhavern for £2 4*s.* for professional attendance and medicine. Defendant stated that he was entitled to the services of the medical man by virtue of his membership of the club at the dynamite works, Perranporth. Plaintiff said he made a verbal arrangement with the dynamite company to attend the members of families resident at home of men who paid into the club. In this case he attended defendant's daughter, who had been earning her living as a domestic servant, and had come home and died, and he regarded that as outside the scope of the club. His Honour said if a daughter lost her situation and went back home it would be a serious burden on the family. On the other hand, if the arrangement included all children who went back home, it would be a great increase of work to the medical man. There should be a contract in plain writing, so that it should be known what it included. If the girl did not come in the club then she was personally liable, unless it could be shown that the medical man had the defendant's express authority to attend her. Judgment was eventually given for defendant with costs.

Reviews and Notices of Books.

The Sequels of Disease, being the Lumleian Lectures delivered in the Royal College of Physicians, 1896, together with Observations on Prognosis in Disease. By Sir DYCE DUCKWORTH, M.D.Edin., LL.D., F.R.C.P.Lond. London: Longmans, Green and Co. 1896.

RAPID as has been the progress made in respect to knowledge of the nature and phenomena of disease, there is, at any rate, one chapter which is yet but imperfectly written. There is very much still to be learnt concerning the correlation of diseases, or, in other words, the altered conditions which are established by even the most transient and apparently trivial departures from the normal activities of the body. Had we clear knowledge on such matters there might be less need to veil our ignorance by the use of such phrases as imply special proclivities or morbid tendencies, and we should be enabled to understand the meaning of many of those states that now go by the colourless designation of "sequelæ." It was therefore a happy notion of the Lumleian Lecturer of 1896 to devote his lectures to an exposition of present knowledge concerning the sequels of diseases, thereby accumulating facts which may enable us to make some kind of generalisation in a subject that contains so many and various elements. Moreover, the subject has seldom before been regarded from this wider point of view, and its complexity somewhat baffles definition. This much, at any rate, is clear—namely, that a "sequel" may be due to the continued operation of the primary agency, even though separated by a long interval of time from the original disease; or, on the other hand, it may be a fresh derangement entirely, which would not, however, have occurred had not the organism been rendered vulnerable by the changes wrought in it by the previous disorder. It is only in some such sense that one derangement can truly be said to be the sequel of another, and yet in point of fact it is by no means easy to assign the real origin of the secondary affection. Syphilis is a notable example of the long persisting operation of a specific agency, and yet there are morbid conditions which may supervene in those who have been infected which can in no way be referred to the direct action of the virus. It must be more than a fortuitous circumstance that so large a proportion of tabetics should have years previously been the subjects of syphilis, but neither in its pathology nor in its amenability to treatment can spinal sclerosis be regarded as a syphilitic lesion. The numerous sequels of acute infectious diseases—especially those involving the vascular and the nervous systems—cannot in the majority of instances, be referred to the direct operation of the toxine; yet it is impossible to doubt that in some way or other these tissues are rendered by its influence more prone to subsequent inflammatory or degenerative changes. Then, too, one infectious disease may apparently render the body more vulnerable to another infection, as in the liability to tuberculosis so commonly seen after measles, and sometimes after influenza or typhoid fever. Sir Dyce Duckworth naturally devotes most space to a consideration of the sequels of specific infectious diseases, but he also shows that many local disorders have their sequels too. His general summary may be taken as merely provisional, but as offering some means of classifying the various kinds of sequelæ that are met with. These he groups in five categories: (1) The *bacterio-toxic*, which may be early or late, direct or indirect, the last-named ascribable to fresh or secondary infection; (2) the *revealing* sequels, wherein a latent or dormant taint or tendency is first evoked by the occurrence of an acute illness; (3) the *nervous*, of which trophic and sensory disorders are the chief; (4) *chemico-toxic*, as seen in cases of chronic metallic poisoning; and (5) *direct non-toxic* or residual

Hosted by Google

sequels. As a contribution to a difficult subject, and as stimulating its study, these lectures should be of value. They are supplemented by an essay on Prognosis in Disease, a vitally important subject, which is treated in a manner to be expected from a physician of ripe clinical experience and sagacity.

The Toxic Amblyopias: their Classification, History, Symptoms, Pathology, and Treatment. (The Alvarenga Prize Essay.) By G. E. DE SCHWEINITZ, A.M., M.D., Professor of Ophthalmology in the Philadelphia Polyclinic. With Forty-six Illustrations and Nine Plates. Philadelphia: Lea Brothers and Co. 1896. Pp. 238.

WHEN the diseases of any organ have been roughly classified, and the principles of their treatment established by long experience, few things more useful can be undertaken than to collect and compare isolated cases described by different authors in books, journals, and reports of societies in which certain symptoms have formed prominent features. By arranging such cases in groups conclusions can sometimes be drawn which may prove of the greatest service in establishing correct diagnosis, and in leading as a result to appropriate treatment. Such service Dr. Schweinitz has rendered to Ophthalmology in the work before us. The extensive bibliography with which each chapter closes shows that he has been most industrious and painstaking in ransacking every publication (and their name is legion) in which reports of cases of toxic amblyopia can be found, whilst the text shows he has taken infinite trouble in mastering their contents. There is, in addition, a considerable amount of original investigation, the author having performed many experiments on animals with reference to the effects of alcohol, quinine, salicylic acid, and filix mas in inducing amblyopia and amaurosis. The classification adopted by Dr. Schweinitz is essentially physiological, and he has brought together notes and observations on no less than eighty-six agents, including those which act as mydriatics, or those which are myotics, those which are nervous sedatives, like acetanilid and phenozone, various anthelmintics, and ptomaines. Dr. Schweinitz appears to entertain no doubts in regard to the existence of alcoholic amblyopia, and observes that most of the investigations show that the anatomical basis of this affection consists of an augmentation of nuclei, hypertrophy of the connective tissue, and wasting of the nerve fibres of a limited portion of the optic nerve, known as the papillo-macular bundle; in fact, that there is an interstitial sclerosing inflammation comparable according to Samelsohn, to the same pathological process which alcohol produces in the liver—for example, an interstitial hepatitis. This statement is supported by the drawings of Nettleship and Edmunds and of Uhthoff. The evidence of the existence of tobacco amaurosis seems to us to be overwhelming, and although apparently many men habitually smoke to excess without experiencing discomfort, yet much allowance must be made in regard to the particular kind of tobacco used, some kinds, as the Havana, only containing 2 per cent. of nicotine, whilst Virginian tobacco contains close upon 7 per cent.; and also allowance must be made for the density of the cigars used, and, in addition, for the particular mode in which smoking is conducted—that is, whether it is simply taken into the mouth and expelled, or whether it is discharged through the nose, or is allowed to enter the lungs, in both the latter cases being brought into contact with a much larger extent of surface. The period of the day also exerts an influence—whether the tobacco be taken before or after meals. Most smokers can probably use without harm from two to three ounces weekly, but idiosyncrasy is an important factor. A larger quantity and stronger tobacco can be consumed in the form of a cigar than in that of a pipe, perhaps owing to the larger formation of volatile bases in the latter case. Though some, like Mr. Hutchinson, have thought that alcohol was antagonistic, others, and with these Dr. Schweinitz is inclined to agree, believe that alcohol freely used with tobacco predisposes the patient to central amblyopia. It is remarkable that certain races, as the Turks, the South Americans, and Cubans, are not liable to tobacco amaurosis. The proper treatment of this affection is total abstinence from tobacco and alcohol, the administration of strychnia, and, perhaps, the application of voltaic electricity. Dr. Schweinitz remarks that the "great consumption of tobacco by sailors and railway employés renders it desirable that examinations for central scotoma should be made among those who are obliged to watch coloured signal lamps." There is an interesting section on Quinine Amaurosis, and it is stated that usually the dose which causes blindness is a large one, but it has varied from fifteen grains to an ounce in twenty-four hours; yet enormous doses—e.g., one ounce—have been taken without disastrous results. The ophthalmoscopic symptoms are that the disc is pallid and the arteries very small, with in many cases a greyish haze of the retina and a cherry-coloured spot in the macula, the appearances resembling those of embolism of the central artery. Many drawings illustrate the extent of the scotomata observed in different cases and of the microscopic appearances of the nerve. We commend to our readers the chapters on Lead and Carbolic Acid Poisoning. Altogether, the work, which must have involved a large amount of labour, is one that should be carefully studied by every ophthalmic surgeon, and it fills a hiatus in the wide subject of ophthalmic disease.

Pioneers of Evolution, from Thales to Huxley. By EDWARD CLODD. London: Grant Richards. 1897.

THERE is not a more fascinating subject than the evolution of "Evolution," and despite the comparatively small size of the volume before us the author has not shorn the subject of one whit of its absorbing interest. We have read this volume with considerable pleasure, giving, as it does, a concise, but none the less clear and complete, account of the history of the origin of species. In it are illustrated the wide fluctuations of human thought and the pernicious influence upon advancing knowledge which certain deep-rooted and erroneous ideas have effected. Dealing in historic sequence with the pioneers of evolution, from Thales to Huxley, the author has interposed a trenchant chapter on the Arrest of Enquiry. It is here that the author shows more animation than when he poses as a mere historian. He is caustically emphatic upon the obstacles placed in the way of advance by the teachings of the Church. "Between birth and revival there were," he says, "The centuries of suspended animation when the nepenthe of dogma drugged the reason." And so the arrest of enquiry occurred between the dates A.D. 50 to A.D. 400, when the Christian doctrine was founded and developed. In all that pertains to these doctrines the author is, of course, a very decided sceptic. He does not, however, in the chapter on Modern Evolution, following that upon the Renascence of Science (A.D. 1600 onwards) improve his position as a controversialist. However right and correct he may be in his views, it is hardly respectful to speak of Dr. Butler as a "desiccated pedagogue" because he publicly rebuked Darwin for wasting time on such useless subjects as, Dr. Butler thought, were experiments in chemistry. Then, again, whilst showing very distinctly that Wallace was the first who conceived the idea of the survival of the fittest, and according him, as Darwin also did, the honour of the conception, still, because Mr. Wallace would not allow that natural selection explains the origin of man's spiritual and intellectual nature, Mr. Clodd regards him as not keeping his first estate and as dropping out of the ranks of the pioneers of evolution. Yet of Mr. Wallace's work Darwin said: "Your words have come true with a vengeance; that

Hosted by Google

I should be forestalled," &c. And again: "So all my originality, whatever it may amount to, will be smashed, though my book, if it will ever have any value, will not be deteriorated, as all the labour consists in the application of the theory." We suppose Mr. Clodd would discount equally the work which many eminent men of science of the present day have done who happen to hold different views to his own on certain abstruse subjects. He backs his arguments on the absurdity of entertaining any faith in psychical phenomena by alluding to certain exposures of the tricks of spiritualists. It is to be admitted that in this field there has been much that has been shown to be fraudulent, but the author exhibits prejudice surely by cynically remarking that these things are done "of course in the dark." A scientific thinker must admit all conditions in experiment if he is to make accurate deductions. The luminous property of phosphorus and of other substances can only be made evident by viewing them in the dark, and more recently the existence of a new form of matter in the x rays was only made manifest by photography or by using a fluorescent medium in a darkened chamber. To admit arguments of this kind we are asked to admit also that the degree of conception or insight of all men is the same, but we should have been still in the dark as to the origin of species if some men's insight into the nature of things had not been keener than that of their fellows. The student of science can, after all, only express belief or disbelief, he can never assert positively what is impossible. There are things beyond the mental gamut. The acutely sensitive photographic plate records the existence of more stars than the eye can see, and which is to be believed?

We may point out to the author that Professor Poulton has, in the April number of *Science Progress*, drawn attention to a remarkable anticipation of modern views on evolution which is seen to occur in the writing of "that great pioneer of modern anthropological and ethnological research," James Cowles Prichard, who was born at Ross, in Herefordshire, in 1786. His conclusions in his second volume of researches into the physical history of mankind (second edition, 1826) on the transmission of acquired characters appear to be identical with those independently arrived at by Professor Weissmann over half a century later. Professor Poulton remarks at the end of his paper that sufficient has been said to prove that the author was one of the most remarkable and clear-sighted of the predecessors of Darwin and Wallace. In view of this conclusion the name of Prichard is well worthy to be added to the list of the pioneers of evolution.

The book is illustrated with four admirable portraits, by the Swan Electric Company, of Darwin, Wallace, Spencer, and Huxley. It contains a very readable and interesting history of the growth of thought on the origin of species, and those who have little time to devote to the study of the well-known large and ponderous works should avail themselves of the opportunity of intellectual cultivation which this book offers.

LIBRARY TABLE.

Archives de Physiologie. Publiées par MM. Bouchard, Chauveau, et Marey. Cinquième Série. Tome ix., No. 2. April, 1897.—The more important articles amongst the twenty that are contained in this part of the Archives de Physiologie are as follows:—M. Charles Rouget writes on the Histology of the Terminal Fibres of the Motor Nerves in the Striated Muscles of Amphibia. These he has rendered visible by the employment of methylene-blue, and shows both by description and in drawings that they are arranged in a helicoidal manner and present a moniliform aspect. M. A. Chauveau gives an account of a method of demonstrating that in living muscle positive work subtracts from, whilst negative work adds to, the energy of the motor, as it does in the inanimate world. M. A. Imbert discusses the mechanism of muscular contraction, and associates it with the superficial tension of liquids. M. F. Laulanié gives the results of his experiments on varnishing rabbits and the causes of death. Death ensues, he shows, owing to increased radiation of heat and consecutive disturbance of the digestive functions. M. J. Lefèvre publishes his Calorimetric Researches on the Mammifers, from which he deduces certain general laws of refrigeration by means of water. He shows that the lower the temperature to which the animal is exposed the quicker does its temperature fall. M. C. Delezenne supplies a long article on the Coagulation of the Blood in Birds, the conclusion he has arrived at being reserved for a future paper. MM. Mairet and Vires contribute an article on the Toxicity of the Liver, which they show to be considerable. MM. E. Wertheimer and L. Lepage describe their attempts to discover the mode of absorption of the liver pigments, and are satisfied that it is chiefly accomplished through the blood and not through the lymphatic vessels. M. J. Laudenbach of Kiev continues his Investigations on the Hæmopoietic Function of the Spleen, and has satisfied himself that the spleen does take part in the formation of hæmoglobin and in the maturation of the red corpuscles of the blood. M. Doyon gives the results of his researches on the motor and inhibitory nervous supply to the muscular tissue in the lungs. He finds both sets of nerves in the vagus. M.M. D. Courtade and J. F. Guyon have investigated the motor influence exerted by the great sympathetic nerve. They demonstrate that this set of nerve-fibres causes relaxation of the longitudinal and contraction of the circular fibres. M. Ch. A. François-Franck and L. Hallion continue their researches on the vaso-motor innervation of the liver. M.M. A. Dastre and N. Floresco supply "A Contribution to the Study of Bilirubin," and show that bilirubin does not exist in a free state in nature, but in combination with alkalies forming alkaline bilirubinates.

Fads of an Old Physician. By GEORGE S. KEITH, M.D., LL.D., F.R.C.P. Edin. London: Adam and Charles Black. 1897. Pp. 173. Price 2*s.* 6*d.*—This is practically an improved and enlarged edition of the "Plea for a Simpler Life," which was reviewed in our issue of Jan. 18th, 1896 (page 171). On that occasion we referred to the absence of "instructions for the guidance of individuals in ordinary health," but Dr. Keith has now supplied what is wanting by giving an outline of his daily dietary. His chief meal is dinner at 7 P.M., consisting of vegetable soup or fish-soup, followed by fish (not more than 3 oz.) with a potato and always another vegetable, stewed fruit with cream, or pudding, or fruit tart. If there is no fish an ounce or two, certainly not more, of lamb, game, rabbit, or tripe may be taken once or twice a week. Dr. Keith has followed this system for about forty years, is now seventy-eight years of age, and finds that he enjoys good health. He has much to say on the manifold benefits of drinking hot water; with respect to alcohol he counsels abstemiousness, but not prohibition. His *menus* would inevitably be anathema to the average diner-out, but, on the other hand, many dyspeptics and victims of the uric acid diathesis would probably benefit by them.

Dental Surgeon's Daily Diary and Appointment Book for 1897. London: John Bale and Sons and Claudius Ash and Sons. Pp. 224. Price 6*s.*—This diary is a well-bound volume of quarto size and nearly square; the paper is of good quality; the ruling and printed headings are so planned that six week-days are shown on each alternate opening, three lines being left for the entry of engagements at each hour from 9 A.M. to 6 P.M.; the intervening openings are reserved for memoranda, a few lines being set apart for the Sundays. The alphabetical index is ample and the diary is well adapted for professional use.

The Ethics of Diet. Revised and Enlarged Edition. By HOWARD WILLIAMS, M.A. London: Swan Sonnenschein and Co. and The Ideal Publishing Union, Limited. 1896. Pp. 597.—This well-written and thoroughly readable book contains much that is interesting from a literary and historical point of view. The author seeks to inculcate vegetarian principles by arguments taken from the works of numerous writers, ancient and modern, his copious quotations being dexterously managed, so that the narrative is never disjointed, prosy, or dull. Physiological questions are scarcely introduced, "kreophagy" being condemned on the grounds that it is both cruel to the lower animals and debasing to mankind. Some of the patristic writers are included among the authorities relied on, but there is naturally no reference to the passage in the Epistle to the Romans where St. Paul remarks that "One believeth that he may eat all things; another, who is weak, eateth herbs."

The Matron's Course: an Introduction to Hospital and Private Nursing. By Miss S. E. ORME, Lady Superintendent, London Temperance Hospital. London: the Scientific Press. 1897. Pp. 87. Price 1*s.*—This little book consists of twelve lectures which give a clear and easily understood view of the things requisite to be learned by a nurse. It is not overloaded with anatomy and physiology, but deals with matters of practical utility, such as disinfection, bed-making, the prevention of bed-sores, the administration of food, details of the attention required by a patient, the observation of symptoms, &c. There is also much judicious advice on the subject of a nurse's general demeanour, but, strangely enough, there appears to be no reference to bathing, except as a method of treatment in typhoid fever.

Madeira and the Canary Islands. By A. SAMLER BROWN. Fourth Edition. London: Sampson Low, Marston, and Co. Cape Town and Johannesburg: J. C. Juta and Co. 1896. Pp. 267. Price 2*s.* 6*d.*—This convenient volume can be recommended to all who wish for information on the subject of Madeira, the Canary Islands, and the Azores. It contains copious lists of the steamers which call at the various ports, maps of Madeira, and of each of the Canary Islands, hints useful both to visitors and residents, whether invalids or not, details of excursions over all the islands, a long account of their commercial position and productive capabilities, past and present, and, in order that nothing may be wanting anywhere, a sketch of their history from the earliest times since their discovery in the first half of the fourteenth century.

JOURNALS AND REVIEWS.

The Practitioner. Dr. J. F. Goodhart, writing on Appendicitis from a Physician's Point of View, gives an interesting and instructive review of numerous cases which have come under his observation. Mr. C. A. Morton of Bristol describes a case of Cholecystotomy in which, finding that it was impossible to bring the gall-bladder to the wound in the abdominal wall, he adopted a recommendation made by Mr. Mayo Robson, and united the parietal peritoneum to the edges of the incision in the gall bladder; before doing this, however, it was necessary to peel the peritoneum off the under surface of the abdominal wall. With a view to increasing the coagulability of the blood, he administered a two-drachm dose of chloride of calcium by enema a few hours before the operation. Dr. G. E. Herman writes on the Kind of Instruction Suitable for Midwives, and Dr. A. G. Miller on the Radical Cure of Hernia. The "Causerie" discusses a financial aspect of surgery in the fourteenth century, and is highly amusing.

Journal of Balneology and Climatology.—The British Balneological and Climatological Society, although of comparatively recent origin, has been so well supported that it finds itself in a position to bring out a quarterly journal devoted to its special subjects. The first number appeared last January, with seven original articles, useful editorial articles and notes, reviews of a number of books, and lengthy reports of two meetings of the Society. The first of the original articles is on Balneology, Old and New, by Sir Edward Sieveking. It is followed by Dr. A. S. Myrtle's Presidential Address delivered at the opening of the second session of the Society last October, after which come short papers on Natural Mineral Waters by Mr. W. H. Pearce, and on the Climate of Ilfracombe by Dr. C. W. E. Toller. Dr. William Ewart contributes a long article, largely historical, on the Decrease of Ague and Aguish Affections in London, and Mr. D. E. Flinn writes on Wintering Stations in Ireland. Most of the papers in the second number are practical ones on the treatment of pulmonary phthisis and gout. Dr. Samuel Hyde, the editor, urges the railway companies serving health resorts to charge lower fares. The journal is published in the middle of January, April, July, and October by Messrs. John Bale, Sons, and Danielsson, 85–89, Great Titchfield-street, W.; it contains rather more than 100 pages, royal octavo; the price is 2*s.*

Le Vélo Médicale.—Cyclists contemplating expeditions in France will find a variety of useful information in this journal, which is brought out monthly under the auspices of the Union Médicale Vélocipédique et Athlétique de France. Dr. Oscar Jennings is president of the association, and has published articles on "Cyclotherapie" in the paper. The office is at 26, Rue Joubert, Paris; the price of the journal is fifty centimes.

New Inventions.

A NEW BOUGIE-CATHETER.

THE Medical Supply Association of Edinburgh have manufactured, at the suggestion of Dr. Cuthbert Bowen, of the General Hospital, Barbadoes, a set of silver bougie-catheters which are a decided improvement on any of the instruments at present in use. The advantage claimed for these bougie-catheters over simple catheters is in the facility with which they can be cleaned and rendered aseptic, the apertures being in the blunt end of the bougie, and not at the side as in the ordinary silver catheter. These instruments, as their name implies, are capable of being used either for gradual dilatation of the urethra in stricture or for the withdrawal of urine in cases of simple retention. By the removal of a screw plug in the handle the bougie can be instantly converted into a catheter, all uncertainty as to whether the instrument is in the bladder being removed by the flowing of urine through the handle. These instruments run in sizes from 1 to 21, the gradations being extremely gradual; thus the advantages of the bougie are retained and the disadvantages of a catheter avoided.

UNIVERSITY OF LONDON.—The following examiners for the year 1897–8 were elected at the meeting of the Senate held on April 28th:—Experimental Philosophy: Professor G. F. FitzGerald and Professor Silvanus Thompson. Chemistry: Professor Wyndham R. Dunstan and Professor William Ramsay. Botany and Vegetable Physiology: Professor J. Reynolds Green and Professor J. W. H. Trail. Comparative Anatomy and Zoology: Mr. F. E. Beddard and Mr. W. Maxland Benham. Practice of Medicine: Dr. W. H. Allchin and Dr. Frederick Taylor. Surgery: Mr. William Anderson and Mr. Henry Morris. Anatomy: Professor D. J. Cunningham and Professor G. D. Thane. Physiology: Professor E. A. Schäfer and Professor William Stirling. Obstetric Medicine: Dr. G. Ernest Herman and Dr. Peter Horrocks. Materia Medica and Pharmaceutical Chemistry: Dr. Sidney Phillips and Dr. W. Hale White. Forensic Medicine: Professor J. Dixon Mann and Dr. Thomas Stevenson. State Medicine: Dr. Edward Seaton and Dr. Arthur Newsholme. Mental Physiology: Professor S. Alexander and Dr. T. Claye Shaw.

THE LANCET.

LONDON: SATURDAY, MAY 8, 1897.

THE Public Health (Scotland) Bill has begun what will probably prove a slow progress through the Grand Committee stage. Notice has already been given of over sixty pages of amendments, and the list is still being added to. We are glad to observe that they include proposals intended to obviate nearly every one of the defects to which we called attention in a recent article.[1] The formation of port sanitary authorities, the levelling and macadamising of private streets in populous places, the prevention of wakes in fatal cases of infectious disease, and the prevention of railway manure nuisances even when the nuisance arises in connexion with covered trucks are dealt with in suitable amendments. A number of valuable clauses are set down in the name of Sir WILLIAM PRIESTLEY. Sir CHARLES CAMERON is also a member and should be useful, but it is very unfortunate that Dr. FARQUHARSON, in proposing that the Bill should be remitted to a Committee, thereby effected his own exclusion from its deliberations.

The opening meeting on Tuesday last was in some respects satisfactory and in others the reverse. Certain of the proposals made were of a distinctly retrograde character, and one of these was carried, though only by a very narrow majority. In the clause dealing with the appointment of medical officers and sanitary inspectors, one Member made an extraordinary suggestion for the deletion of the stipulation that local authorities "shall allow to every such medical officer and every other officer or clerk appointed by them on account of his employment a proper salary." It did not appear whether the honourable Member thought that the withholding of a proper salary from a competent official, or the appointment of an official so incompetent that he should not deserve a proper salary, would be the better course to adopt in the sacred cause of economy. Anyhow, the amendment was rejected out of hand. It is unfortunate that a proposal advocated by Sir ROBERT REID did not meet with the same fate. At present every new medical officer of health must be the holder of a Diploma in Public Health. It seems that if a vacancy were to occur in a particular town which Sir ROBERT REID represents none of the medical men in practice there would at present be in a position to accept the office, and he urged that the town might in consequence require to bring a man from a distance and pay him a large salary to devote all his time to his duties. The risk is imaginary. The examinations in State Medicine are not prohibitive to a man in practice; and a practitioner who will not take the trouble to study the subject and obtain a qualification has no claim to a new office, which should always be filled by a man who has sufficient belief in the value of sanitation and sufficient perseverance to carry him through the required examination. If by chance any community were without such a man, there are now plenty of qualified applicants even for small salaries. Whether the local authority, which seems to have made a representation to Sir ROBERT REID, had any fear of being compelled to avail itself of the services of a county officer, we know not, but in the interests of administrative uniformity no such fear should have had any weight given to it. In the end, however, the proposal that the Local Government Board be permitted to sanction the appointment in burghs of unqualified officials was agreed to by a majority of two votes, including that of the LORD ADVOCATE, who then blandly inquired whether it was desired to allow the same liberty in the case of county health-officers. We hardly think the Committee will desire anything so reactionary, but the fact is that a genuine sympathy with public health is the first qualification for any Committee or Government which wishes to pass a useful Bill, and in such a matter slackness in detail is likely to be interpreted as due to weakness of principle or to unexpressed dread of sanitary progress.

Whether there will be any further tendency to sanction administration by incompetent and unqualified officials remains to be seen. The opportunity, however, is afforded by a document issued to the Committee by sanitary inspectors in Scotland. It certainly tends to justify the complaint made by Dr. BRUCE in a letter which we publish elsewhere. Anyone acquainted with English methods will hardly believe that in Scotland sanitary inspectors venture to ask Parliament to confer on them the statutory right, in the case of manufactories, buildings, and premises used for trade purposes, to certify what is "a nuisance or injurious or dangerous to the health of any of the inhabitants." It is obviously preposterous that certification of anything as a nuisance or dangerous or injurious to health should be given by anyone but a thoroughly qualified medical man, or by a group of people who feel that their health is actually being injured, as provided for in the clause contained in the Bill. Even in the latter event we can hardly suppose that any local authority would think of acting in the absence of a report from its medical officer. In the same "memoranda" there are various suggestions of a similar character, some of them almost amounting to a proposal that the sanitary inspector should usurp the place of the local authority.

One naturally turns to the Scotch Acts to ascertain what are the special qualifications required of sanitary inspectors which give them any kind of justification for the claims which they advance. The new Bill makes reference to "qualifications set forth ..... in Section 54 of the Local Government (Scotland) Act, 1889." But on turning to this Section, and to the existing Public Health Acts, and to the Burgh Police Act, the fact emerges that the law requires no qualification of any sort whatever for any sanitary inspector appointed by any local authority, urban or rural, in Scotland. In the case of a county council, the person appointed as sanitary inspector must have had three years' experience under a local authority. A county council, however, is not a local authority for administration of the Public Health Acts, and, we repeat, the law demands no examination or certificate

[1] THE LANCET, Feb. 13th, 1897.

Hosted by Google

of any kind for sanitary inspectors of local authorities. At the same time, it is just as sanitary inspectors of local authorities that they request power to certify as to what trades, &c., are nuisances within the meaning of the Acts. Seeing that the law requires no qualification for sanitary inspectors, we turn to the document issued by themselves for evidence of competence for such work. It may be assumed that the paper is the outcome of the deliberations of the principal inspectors, and the positions occupied by the signatories support the assumption. Yet the production bears on the face of it evidence that the writers are not acquainted with the most elementary rules of English grammar. They tell us that a particular section of an Act "has been found to work satisfactory." They declare, in small capitals, that "the meeting of local authorities occur either once a fortnight or once a month." In one line "the Council ..... were gratified" and in the next "the Council submits," and so forth. Most absurd of all, regarding Clause 89 they endeavour to instruct the Committee itself in grammar, telling it to delete "that purpose" and insert "these purposes," the matter in question being "a proper supply of water for the use of lodgers." The terminal "s" in lodgers has been enough to lead the whole association of sanitary inspectors astray! One member of the Committee scouted the idea of sanitary inspectors in Scotland being placed in the same category as nuisance inspectors in England, and in doing so he paid only a left-handed compliment to the latter set of officials.

Facts, however, must be faced as they stand. The Government declares that while it will not directly subordinate sanitary inspectors to medical officers its policy is to allow local authorities, subject to the consent of the Local Government Board, to "regulate the duties of ..... medical officers and sanitary inspectors and their relations to each other, whether appointed before or subsequent to the commencement of this Act." This concession is better than nothing. If it is to have the very slightest value in urban districts it is obvious that those Sections of the Burgh Police (Scotland) Act of 1892, which already lay down the duties of medical officers and sanitary inspectors, will require to be repealed. How much they stand in need of repeal may be judged of by Section 75, which runs thus: "The Commissioners shall appoint a sanitary inspector, subject to the provisions of the Public Health Acts, whose duty it shall be to enforce the sanitary provisions of such Acts and this Act." Let it be observed that the term "such Acts" will include the present Bill when it becomes law, and that the law does not require of the sanitary inspector any kind of qualification, but that it does require of every newly appointed medical officer a diploma, not only in medicine, but also in public health. Yet in a newly formed burgh the man who was yesterday plastering a wall or sawing a plank, and who has been similarly occupied during all his working life, is to-day pitchforked into the position of "superintending" the sanitary provisions of the Public Health Acts, while to the doubly examined and certified medical officer are relegated certain duties relating to "the existence of disease" within his district. Mr. W. S. GILBERT never suggested anything more whimsical. We can hardly conceive that the Bill will pass without these clauses of the Burgh Act being erased from the Statute Book.

ANYONE who is privileged to enter the depressing portal of one of our big London infirmaries or workhouses, and who notices the children there, will see some with sore heads and others with sore eyes, who have been there month after month, perhaps year after year, spending the best years of their lives—best, that is, for educational purposes—without any education, and perhaps with harmful associates around them. Yet if these children are sent to, and if they are accepted at, one of the big district schools, they spread, as we mentioned in our leading columns last week, disease amongst the others because of the want of means of classification, and the overcrowding and deficient cubic space. Mr. NETTLESHIP'S letter (dated April 22nd) to the *Times* is well worthy of perusal as an illustration of the evils which result from these schools as regards ophthalmia alone. He mentions there the case of a girl who was under his care on and off from 1873 to 1888 for the results of ophthalmia acquired at one of the schools when she was in the infant department. He says of her: "Her life has been largely spoilt by the disease and the ratepayers put to expense in consequence." Even when the children are cured and sent to one of these schools, some of which contain 1600 or 1700 scholars, they lack anything like personal attention owing to the size of the schools, and owing, as it would appear from the evidence before the Departmental Committee, to the deficiency or the inefficiency of the teaching staff. Hence the want of individuality, the inertness, and sluggishness which characterise the typical pauper child. No one can read the evidence and report of the Poor-law Schools Departmental Committee without becoming aware that grave flaws exist in the administration of these schools, for which, not only the guardians, from whom the managers of these schools are elected, but also the Local Government Board, are responsible. Matters have been going on thus for many years, the number of inspectors being quite inadequate for the work; and it appears from the evidence submitted that it was useless to look for reform either to the managers of the schools or to the Local Government Board. Even when the Local Government Board did make recommendations to the respective managers of schools they were not always carried out, and there existed no adequate means of enforcing compliance (questions 743, &c.). The principal recommendations of the Departmental Committee are:—That a new central authority be appointed for the metropolis, which shall have the control and supervision of *all* the London pauper schools, and *all* the children; that ophthalmic, and other hospital schools be established for the reception of all children suffering from contagious diseases, and that arrangements be made for their education whilst in these institutions; that suitable homes be provided for feeble-minded children on the boarding-out system; and that further provision be made for inspection, additional women inspectors being appointed, who, as a rule, should possess medical qualifications.

On Feb. 20th an important deputation of the guardians

Hosted by Google

and school managers waited on the President of the Local Government Board, who, in reply, stated that it was impossible to leave matters as they were and to ignore the recommendations of the Departmental Committee. The remedy lay between adopting them in their entirety, or in part—viz., by placing only the children medically or physically defective under the care of a new central authority. This latter was the plan he proposed to adopt, and to embody in a draft general order. The special classes of children to be thus dealt with will be those suffering from ophthalmia or other diseases of the eye, disease of the skin or scalp, those requiring convalescent treatment, those presenting physical or mental defects, those ordered by a magistrate to an industrial school under the Act of 1866, probably also those in the *Exmouth* training ship, and those who are boarded out. It is proposed that the new authority shall consist partly of guardians and partly of nominees of the Local Government Board. Such an arrangement will doubtless have some advantages, chief among which is that it will liberate at once a great deal of the accommodation in the existing schools which is sadly needed.

But the medical and the educational evils to which we have referred can only be adequately met by the establishment of a new central board for all the pauper children of the metropolis. Such a board would be more likely to consist of persons really competent and experienced in the education and management of children. They would, in the second place, be more likely to elect competent and sufficient officers to the posts of teachers. They would, moreover, be able to balance between the overcrowded schools and those having vacancies, and would be able to establish separate institutions for the treatment of ophthalmia, ringworm, and the other infectious conditions, to which children are liable. Such a central authority would be the most competent to judge how far the existing schools comply with the real educational needs of the pauper children. Those familiar with the average pauper child know that to give such children interest in their work by cultivating their manual dexterity is the best way to educate their cerebral functions, and if more institutions such as the *Exmouth* training ship were established for the boys and more cottage homes for the reception of limited numbers of girls, there is no doubt whatever that the future of these children would be greatly ameliorated, and in all probability they would thus be saved from a career of crime and attracted to a career of usefulness. The half measures proposed will undoubtedly be some improvement, but nothing short of a more radical reform, such as that recommended by the Departmental Committee, will fully meet the necessities of the case.

THE profession and the public of Birmingham have always taken creditable interest in the subject of hospital reform. Dr. HESLOP, of Birmingham, did much to raise the estimate of club practice. A few years ago a committee investigated the subject and anticipated the principal conclusions which have been reached by later inquirers. Birmingham also was largely concerned in the exposure of the abuses of medical aid associations. It is not remarkable, therefore, that Birmingham is again to the fore in the discussion of the question of Hospital Abuse, and that the profession is giving valuable aid in the promotion of the principal objects of the Hospital Reform Association. If we may judge from the letters in the Birmingham papers the whole community is exercised on the subject, and is probing deeply into the very roots and principles of the hospital system. Last week we reported a meeting of the Hospital Reform Association in Birmingham, presided over by Mr. JORDAN LLOYD, F.R.C.S., surgeon to the Queen's Hospital, Birmingham. The speeches made at this meeting originated the correspondence which has since appeared in the *Birmingham Daily Post*. Mr. LLOYD'S speech on the subject is very valuable. When the hospital surgeons of the country take their proper place in this controversy, and lend a helping hand to their brethren in the ranks of general practice in defining to the public the real place and function of hospitals, the day of reform will not be far distant. Mr. LLOYD was explicit on one point on which erroneous representations have been made, and on which it is of the highest importance that there should be no misconception. Mr. LLOYD said: "*The first purpose of a hospital is to supply the sick with the medical attention which their case demanded, and which they were unable to obtain by reason either of their poverty or of the severity or peculiarity of their malady.*" "Another reason," said Mr. LLOYD, evidently meaning a secondary reason, "for the existence of hospitals—and it was a real reason—was the training of medical men." After this clear deliverance from a prominent hospital surgeon it is unnecessary and somewhat ungracious for people to write in the Birmingham papers as if the profession maintained the contrary opinion, that hospitals existed first for the education of medical men and that the advantage of the poor was only a secondary reason for their existence. The fact is palpably as Mr. JORDAN LLOYD states it. Subscribers and governors of hospitals are mainly laymen. One of the last things they think about is the promotion of medical education. They subscribe because they wish to help to provide a bed for a poor sick man, woman, or child. Occasionally there is a selfish object at the bottom of this apparent charity, but we will not libel the generality of subscribers by doubting that they contemplate the relief of an urgent case of disease or accident which can not be accommodated at home.

We are not denying the use of hospitals as centres of medical education. These they undoubtedly are, and the poor as well as the rich benefit by the opportunities thus afforded for teaching. But this *métier* of hospitals is a secondary one. Medical education would take care of itself if there were no hospitals at all. In some conceivable respects it would or might fare better. But undoubtedly in present circumstances hospital practice is an enormous and valuable means of education, though the very popularity of hospitals shows that this means is used humanely and in subordination to the primary purpose of serving and treating the poor. Mr. LLOYD entirely approves in principle of a Central Hospital Board, and proposed a resolution averring that the question of hospital reform should be dealt with without further delay by the lay managers and acting staffs

Hosted by Google

of our various hospitals and dispensaries, and that the recommendations of the Hospital Reform Association for the better regulation of the out-patient and casualty departments are worthy of close consideration. He and Dr. ISAMBARD OWEN differed as to the degree in which the number of out-patients could be restricted. But this is a matter of detail and of experience on which there need be no permanent difference between men who with equal earnestness defend the essential principle that hospitals are not for the general accommodation of the public, or even of the poor, but for selected cases, incapable of proper treatment at home, and for the patient who is unable to command at his own expense the skill which his case requires. One other opinion of Mr. JORDAN LLOYD, expressed with much confidence, should be noted—his conviction, after years of thought, that there are more economical ways of administering hospitals than are now practised. This is, and has long been, our own opinion. But it is only fair to remember that some of our best hospitals are administered with an economy contrasting vividly with the costly management of State-aided or rate-supported institutions.

One of the correspondents of our contemporary, the *Birmingham Daily Post*, Dr. FELIX VINRACE, shows with great clearness the tendency to a complete change in the conception of the character of hospitals. Instead of being regarded in the sense which we have expressed above, they have come to be considered by many of the working classes as institutions in which they are entitled to be treated for trivial ailments. This is a misconception entirely unworthy of the British workman, and the sooner he is undeceived by the medical profession the better. He was never more able than he is to-day to offer proper terms for ordinary medical attendance on himself and family and to contribute a small subscription for the help of those whose extreme cases require exceptional skill and hospital accommodation. Is the thriving working man to be entirely exempted from the duty of such a subscription as he can afford to charities that are almost the monopoly of his order? On one important point, however, we entirely agree with Dr. VINRACE. The principle of compulsion must not be applied to working men. Their contributions must be voluntary, and the pressure of the employers and foremen must be restrained. Working men have the same right to freedom in supporting a medical charity which others have, and to make their contribution a matter of compulsion is to spoil it of its charm and to foster the misconception which if not corrected threatens to turn our hospitals into cheap dispensaries.

AN EXHIBITION AT ARCACHON.—We are asked to announce that an International Exhibition of Hygiene, Food, Commercial Produce, and the Industrial and Fine Arts will be opened at Arcachon, near Bordeaux, on July 15th. The exhibition will remain open until October, and all information can be obtained on application to the Direction de l'Exposition, Arcachon-les-Bains, Gironde, France. Arcachon is a thriving watering-place with a large *clientèle* and more than the usual local attractions, so that the founders of the exhibition look forward with some confidence to successful results.

Annotations.

"Ne quid nimis."

THE CALAMITY AT PARIS.

THE disastrous fire which occurred upon May 4th at a charity bazaar at Paris was a fatality peculiarly distressing in its surroundings. Loss of life is always a thing to be regretted, but how much the more in a case like the present, where the victims had assembled together to do their utmost to assist their poorer brethren and sisters. There are various theories as to the cause of the fire; but, however it arose, the flames spread with appalling rapidity, and in some twelve minutes about 150 persons lost their lives. Most of them seem to have been women, but the reports state that the remains found were so charred and disfigured that recognition was in most cases impossible. We can but offer our sympathy to the relatives and friends of the victims, and suggest that in some cases at least the cause of death would be suffocation and not burning, a death, therefore, unaccompanied by bodily pain; but the accident is a heart-rending one, and of the dead we can but say, "Quorum animis propicietur Deus."

THE TREATMENT OF HABITUAL OFFENDERS.

THE unfortunate people who continually reappear before the police magistrates and petty sessions on various minor charges have for a long time been the despair of the philanthropist and the social reformer. The law does not permit more than the infliction of a trivial fine or a few days' imprisonment, the inefficacy of which penalties is sufficiently proved by an early repetition of the offence. The opportunities provided by numerous "homes" and other benevolent agencies seem equally to fail in reclaiming these habitual offenders, and the principle of sentencing them to progressively increased periods of detention—a principle which has for long been advocated by the Howard Association—is at least deserving of trial. The Association argues that the correction of bad habits requires time, and that hitherto the victims of evil habits have been positively encouraged by a system of sentences which has rendered their reformation impossible, and has (at enormous and utterly wasted cost to the public) made them worse instead of better. These repeated short sentences have been strongly condemned by departmental committees of Government on English prisons and Scotch habitual offenders. The Scotch committee made it their chief recommendation that persons who have been three times imprisoned within one year should, on a fourth conviction in the same year, be deemed habitual offenders, and that if they are again convicted during the ensuing two and a half years they should, in addition to the usual brief sentence of imprisonment, be committed to an adult reformatory or labour settlement for a term of not less than twelve or more than thirty months. It has been found in the experience of all schemes of providing work for the vagrant and habitual offender classes that the majority of such persons will not work continuously unless compelled to do so. This has been the experience of the Dutch and Belgian beggar farms, and, in a great degree, of the Salvation Army farm at Hadleigh, and other similar establishments. There must be compulsion, and also detention for a period long enough to alter bad habits and form good ones. There is no prospect whatever of these labour settlements being made self-supporting, but they would, at least, be far cheaper than the ineffectual system hitherto adopted. The Association considers that the Hadleigh farm has been of great service to respectable and willing workers not of the class

Hosted by Google

of habitual paupers or vagrants, but that farms are unsuitable for habitual criminals, who inevitably corrupt one another; for criminals (as distinct from habitual petty offenders or misdemeanants) gradually cumulating periods of imprisonment are best, one or two years being added for each successive conviction. Habitual tramps and vagrants, and also the class of paupers who constantly discharge themselves from workhouses after a few days' stay, should be checked by compulsory detention for periods adequate to break them of their habits. First offences, or even occasional ones, should be dealt with compassionately, but habitual offences require reformatory discipline, perseveringly applied for adequate periods. Such are the recommendations of the Howard Association, a society which has made the diminution of crime a subject of special study, and the exertions of which in the cause of social improvement are universally acknowledged.

LITERATURE AND SCIENCE.

THE fact that Lord Lister was to preside at the annual dinner of the Royal Literary Fund gave quite a scientific flavour to the 107th anniversary celebration, and no doubt determined the presence at the table of many members of the medical profession. Among the medical men present may be mentioned: Dr. Barnes, Dr. Buzzard, Sir William Broadbent, Sir J. Crichton Browne, F.R.S., Sir Robert Craven, Mr. C. T. Dent, Professor Michael Foster, F.R.S., Mr. Pearce Gould, Dr. J. Gray, Mr. Hutchinson, F.R.S., Mr. G. H. Makins, Mr. Nettleship, Dr. George Ogilvie, Dr. J. W. Ogle, Dr. T. Oliver, Mr. H. W. Page, Sir William Roberts, F.R.S., Professor Sherrington, F.R.S., Dr. S. Squire Sprigge, Dr. Wilks, F.R.S., Sir John Williams, Dr. Theodore Williams, and Dr. G. Sims Woodhead. The speeches in every case rang changes on the connexion of literature with science, or the antagonism of literary work to scientific work. Lord Lister, in the chief toast of the evening, "Prosperity to the Royal Literary Fund," while acknowledging the debt that scientific men, as much as the rest of the world, owe to the author, disclaimed literary merit for his own writings, saying that he was a student of the book of nature, and that the value of anything that came from his pen was due to the grandeur of his theme and not to his treatment of it. The Bishop of Stepney, in proposing the toast of "Literature and Science," found that in the best journalism the two met harmoniously, however opposed they might be in other ways, the search for reality being here the common object of both. Mr. Traill, in responding for Literature, spoke wittily of the function of the critic as a surgical one, "not necessarily followed by the beneficent results with which the name of the chairman would always be associated." There was, he feared "no kindly healing process for a mortified vanity akin to the processes under which the aseptic wound united." Mr. Norman Lockyer responded for Science, and the Earl of Crewe proposed the Chairman's health in suitable terms.

THE APPRECIATION OF MEDICAL SERVICES.

WE have not often to complain of a want of liberality in the higher courts in their estimate of the value of medical service, but in the case of Douglas and Another *v.* Phillips, before Mr. Justice Cave and a special jury, we cannot refrain from such feeling. The plaintiffs, medical practitioners at Hounslow, claimed £105 5*s.* for medical attendance on the defendant, Miss Florence Phillips, who denied that the charges were fair and reasonable. The services and charges were briefly as follows: Consultation at surgery, 5*s.*; five journeys to Richmond at £1 1*s.* per journey; fourteen journeys to London—involving, we gather, a consultation with Dr. Herschell—at £3 3*s.*; twenty-four journeys to Hampton Court at £2 2*s.*; and a journey to London at midnight, £5 5*s.* On the face of it there is nothing unreasonable in these charges. On the contrary, they are moderate. Which of us, which of the jury that reduced this claim to £50 16*s.* 6*d.*, would like to undertake a journey to London at midnight for five guineas? The other journeys to London, which occupied as a rule five hours, were charged for at the rate of only three guineas. Journeys to Hampton Court, which took three hours, only two guineas; journeys to Richmond, which took two hours, one guinea. Several medical men testified to the general reasonableness of the charges. There was, of course, one medical man—all the way from Liverpool—to say that in his opinion the charges were rather high. And he seemed to weigh more with the jury than several others who rightly defended the charges made. The defendant had actually paid £70 altogether into court. Judgment was given for the defendant, the plaintiff to have the costs up to Dec. 4th, 1896, up to which date only £35 8*s.* 6*d.* had been paid into court. An order was made that the plaintiff should take £50 16*s.* 6*d.*, and the defendant take the remainder of the £70 out of court. We cannot think that such an estimate had the serious approval of the judge. Dr. Christian, the member of the firm who attended Miss Phillips, has done right in vindicating by his action the medical estimate of the value of time and service. We regret his unsuccess. But the profession and, we venture to say, men of other professions will accord him their sympathy and approval.

ANTI-VACCINATION AT GLOUCESTER.

THE anti-vaccination party at Gloucester have at last been made aware that they are not to have it all their own way, as they may have fondly imagined from the results of recent municipal and parochial elections. Indeed, the only wonder is that the citizens have been content to allow them to have so long enjoyed freedom from the criticism which their unwarrantable assertions with regard to the sanitation of the city invited. When, owing to the unprotected state of the children from long neglect in enforcing the law with respect to vaccination, small-pox spread in their midst, the anti-vaccinationists proclaimed loudly on all occasions that such neglect of vaccination had nothing to do with the outbreak, which, according to them, was solely attributable to the grossly insanitary condition of the city. This cry—promulgated by such leaders in the anti-vaccination cause as Lieutenant-General Phelps of Birmingham and Dr. W. R. Hadwen—has ever since formed the staple explanation of the Gloucester epidemic amongst those who had been most active in persuading the people to abstain from seeking the protection afforded by vaccination. The utter baselessness of the assertion was amply shown at the time of its first announcement by the city surveyor; but the anti-vaccinationists have continued to adhere to it, thereby damaging the interests of the city, which had suffered so much already from the epidemic. The occasion of the annual meeting of the Gloucester Branch of the Anti-Vaccination League on the 22nd ult. had been intended by the party to have shown to the world how deep a hold their tenets had gained amongst a community which had experienced the trial and suffering of an epidemic of small-pox. The meeting had been widely advertised, and the chair was occupied by Lieutenant-General Phelps, the President of the Anti-Vaccination League. Mr. Milnes, the champion of the cause, and Dr. Creighton, the medical advocate, whose attacks upon Jenner have proved that even a man of science may be blinded by prejudice, had come from London to support the chair and give their benison to the Gloucester stalwarts. The ranks of the latter have been recently reinforced by Dr. Hadwen himself. The citizens, however, were resolved that those who had defamed the city should not enjoy a monopoly of speech

Hosted by Google

on the occasion of this meeting, especially as supporters of vaccination had been directly challenged to reply to the criticisms on the city's sanitation, which had been so freely made. Accordingly, by handbills and posters, the true facts as to vaccination and the refutation of the statements of its opponents induced some to attend the meeting who had no sympathy with its objects. Dr. Bond, the energetic secretary of the Jenner Society, who had been specially challenged, appeared on the platform and obtained a brief hearing whilst he proceeded to demolish the pretensions of Dr. Hadwen to speak of the sanitation of a city in which he was so recent a resident. Another gentleman who essayed to defend Gloucester from the imputations cast upon it was "chucked out," only to re-appear, and after most disorderly scenes to obtain a brief hearing. But the proceedings were not suffered to continue, and disorder reigned supreme, so that the eloquence of Mr. Milnes was lost and the words of wisdom of Dr. Creighton were wasted. We commiserate these two gentlemen on their unfortunate experience, but we cannot say that we are at all surprised at the *fiasco*, which, indeed, was directly provoked by the attitude assumed throughout by the promoters of anti-vaccination in all their references to Gloucester.

THE UNREPORTED DEATH OF A SHIP-SURGEON AT SEA.

MR. S. MASON writes a letter to *Fair-play* which tells a remarkable story of the death of his friend, Dr. W. H. Brendon, on board the steamship *Umona*. The ship arrived in London on March 31st, and as Dr. Brendon's friends received no news from him or information about him they became uneasy, and Mr. Mason was asked to inquire for the missing medical man on April 6th. It so happened that the captain of the ship was in the office, and on being asked if he had had Dr. Brendon on board he replied "Yes." On being asked if he was still on board he replied that he was dead, that he had died on March 17th from dysentery, and was buried at sea on the 18th. On being asked why he or the shipping firm had not communicated the sad fact, he replied that they did not wish to alarm the family, and felt sure that some of the family would be making inquiries. An equally shaky basis of excuse was put forward on the ground of not having the address; but Mr. Mason shows by letters to Dr. Brendon that they had knowledge of his address. A brother had written to the firm to inquire. He was told that the ship had arrived, but no hint was given of the death of his brother. Such consideration for the feelings of a family is most peculiar, and is more honoured in the breach than in the observance. The facts would appear almost incredible if they were not vouched for in a published letter. We cannot imagine that such conduct is common among ship-owners, but we give publicity to these statements so that they may, if possible, be contradicted, and, if not, that they may remain as a unique instance of how not to deal with news so sad respecting the medical officer or, indeed, the humblest passenger or member of the crew of any ship.

CASTRATION AND VASECTOMY IN HYPERTROPHY OF THE PROSTATE.

DR. J. W. WHITE, who introduced the operation of castration for hypertrophied prostate, in a lecture recently delivered states that as oöphorectomy was much abused a few years ago, so is this operation now,[1] and that a similar result in the treatment of appendicitis is threatened. He never encouraged the idea that his operation was a universal panacea. If the patient is not very old, retains his sexual power, has sound kidneys, and only a moderate amount of residual urine, the operation is out of the question and only catheterism is required. If pain is marked and resists small doses of bromide, belladonna, phenacetin, &c., that may be an indication for operation. In such cases vasectomy should be selected. If the residual urine reaches twelve ounces and if it does not diminish under catheterism, the dangers from backward pressure on the kidneys, increasing atony of the bladder, and cystitis are so great that vasectomy is again indicated. In patients with larger prostates, with eight or ten ounces of fœtid or muco-purulent urine, with frequent micturition, and pain on the introduction of the catheter, some operation—vasectomy, castration, or prostatectomy—is indicated. The younger the patient, the greater the sexual power, the sounder the kidneys, and the better the general health, the more the surgeon should incline towards prostatectomy. If the patient is somewhat older and the sexual power is becoming enfeebled vasectomy is to be chosen. Still greater age, with marked renal disease or great failure of health, indicates the same operation. If, however, with the greater age and distinctly lessened sexual power the renal and general conditions are good, castration promises the most benefit with the least mortality. In the worst cases, in which the prostate is enormous, the cystitis excessive, the bladder dilated and atonied, the retention absolute, the kidneys inefficient, and catheterism difficult and occasionally impossible, any operation involves risk. But this must be taken. Castration in these cases is the best procedure. It will occasionally fail, but often the improvement is marvellous.

[1] University Medical Magazine, April, 1897.

A MIDWIFE CAUTIONED.

AN inquest was held at Littlehampton on Friday, the 23rd ult., by Mr. F. W. Butler on the body of Clara Dearing, aged thirty-five years, who had died on the morning of that day. She had been confined of a dead child on the preceding Wednesday. The patient had engaged a midwife to attend her in her confinement. According to the husband's evidence the deceased was well up to the Tuesday evening. It appears that the midwife had seen the deceased on the Saturday and also on the Tuesday before the confinement. Labour apparently began early on the Wednesday morning; the midwife attended as soon as she was summoned, and it seems that when she saw the case she advised that a medical practitioner should be sent for. Mr. Lapthorn attended and gave chloroform, and the patient was delivered of a dead child. In his evidence he said there was a great deal of hæmorrhage, but it is not clear whether this occurred before or after delivery. The patient died early on the Friday morning. Mr. Lapthorn made a post-mortem examination, and as a result of it gave it as his opinion that if medical assistance had been obtained on the Friday or Sunday previously to the confinement the patient would have been saved. The jury found a verdict in accordance with the medical evidence, and suggested that the midwife should be cautioned as to her attendance on such cases in future. Our readers will see that the information given as to the facts of the case is not sufficient for us to form any opinion as to its real nature. Perhaps Mr. Lapthorn will tell us more about it, and especially what the reason was why medical assistance should have been summoned earlier.

EGYPTIAN PRISONS IN 1896.

MANY references have from time to time been made in our columns to the important reforms introduced into the Egyptian prison system since Crookshank Pasha became Inspector-General of Prisons in 1883, and the circumstance that his retirement from that important position has been announced gives additional interest to his official report for the year 1896. During that year the work of the department was carried on under unusual difficulties, owing, firstly, to all grants for the improvement of existing

Hosted by Google

prisons or the building of new ones being withdrawn early in the year on account of the Dongola expedition; secondly, to the want of sufficient accommodation for the continually increasing number of prisoners; and, finally, to the outbreak of cholera during the hottest summer months in seventeen overcrowded central gaols. There was a total of 7954 male prisoners confined in twenty-five principal gaols, seventeen of which were invaded by cholera, while eight remained exempt, and among this large number of persons there were only 116 cases of cholera, with 70 deaths. Not a single case of the disease occurred among the female prisoners, and the Inspector is of opinion that this is due to the fact that they are fed by the department, whereas at all but two of the prisons for males the prisoners' food is supplied by their friends and relatives. Whenever cholera broke out in a prison relatives were strictly forbidden either to visit or to bring in food and clothing for a period varying from one to two months, according to the existence of cholera in the neighbourhood, and invariably the disease was stamped out of the prison in a few days. During 1896 there were over 47,000 unconvicted and convicted male prisoners admitted into the central gaols, and during the same period 36,000 were discharged. Female prisoners were very much less numerous than male prisoners.

MEDICAL MISSIONS IN CHINA.

ALTHOUGH the unwillingness of the Chinese to receive instruction from foreign residents only too often shows itself in outbreaks of murderous violence, it is gratifying to find that the work of the Medical Missionary Association appears to be making progress in some of the towns. At the annual meeting of the Association in Exeter Hall, on May 3rd, Mrs. Bishop, who had been three years in the Far East, stated that at Mukden, the capital of Manchuria and politically the second city of China, the Emperor's uncle and another mandarin caused it to be publicly proclaimed that they had received medical treatment at the United Presbyterian Hospital, an example of aristocratic preference for foreign over native methods which is likely to be beneficial all round. Mrs. Bishop seems not to have been altogether favourably impressed with the sanitary condition of some of the mission hospitals she visited in China, but allowance must be made for the great divergence between Eastern and Western opinion in regard to such matters and also for the danger that patients might be estranged or scared away by too abrupt a departure from their accustomed habits. Even in Bombay, where for more than a hundred years the British Government, possessed of absolute power, has had as free a hand as it is possible to have in dealing with Asiatics, the reports of our correspondents show that public sanitation is still in a rudimentary stage.

DUNLOP TYRES AND PRACTITIONERS' CARRIAGES

OF the comfort of the Dunlop tyre as applied to an ordinary carriage there can be no doubt, and the chief question therefore for those who are anxious to use them is as to whether they will wear. Of course, they require care in using and are somewhat expensive in the first instance, but against these items on the debit side must be set various points to their credit. We have recently received two very opposite accounts of the lasting powers of these tyres, which we here lay before our readers. The first is the experience of a practitioner in Sheffield. He allows that, having procured a set of the tyres in question, he found an enormous increase of comfort from the absence of vibration and jolting, and in addition that the body of his carriage, a light coupé brougham, was saved a proportionate amount of wear. But, on the other hand, he found that they frequently burst and, although mended, soon gave way again; that they threw up a quantity of mud, which injured the paint of the carriage; and that the brakes, though efficient, soon wore out. The other experience comes from a medical officer of health in a hilly part of Wales. He had the pneumatic tyres fitted to an ambulance brougham, which in eight months travelled over 750 miles of hilly, rough ground without a puncture and with extreme comfort to the sick transported thereby. The brake blocks wore out in seven and a half months, but the tyres themselves were but little worn by the brakes, although much cut by the roads. This latter seems a pretty severe test, and we are unable to account for the disastrous experiences of the Sheffield practitioner except by assuming that he got a faulty tyre, for even with the greatest care anything manufactured sometimes fails, or else that the tyres were not properly inflated before use and so got nipped between the road and the wheel. The increase of comfort is so great that though it may not be worth while for a medical man to run the risk of having his carriage laid up for long spaces of time, as happened to one who tried the tyres, yet in the light of the Welsh experience they would seem to be quite worth a trial.

HERNIA OF THE BLADDER.

ALTHOUGH hernia of the bladder was recognised as long ago as 1520, when it was met with by Verdier, yet it has been satisfactorily described only within the last few years. In 1895 fifty-eight cases were collected by Curtis, and in March of this year Dr. Gibson published in the *New York Medical Record* a valuable paper on the subject, containing particulars of forty-five additional cases. From this paper we gather that nearly 25 per cent. of these herniæ were of the femoral variety, and that in more than half of the cases the patients were over fifty years of age. The herniated viscus is often not recognised until it has been opened, and in such cases the mortality is high, for even after deducting those deaths which could not be attributed to the wound of the bladder a fatal result followed in 12½ per cent. It is very probable that the condition is by no means so rare as it is usually thought to be. Dr. Gibson also points out the importance of recognising that traction on the sac of a hernia may draw the bladder into the hernial orifice, and so expose it to the risk of being wounded in an operation.

CHLOROFORM ADMINISTRATION IN WARSAW.

ACCORDING to a paper published in a Russian surgical journal by Dr. Soloveischik chloroform has been administered in 500 cases in Professor Tauber's clinic in Warsaw by Junker's inhaler—Krohne and Sesemann's pattern—with very satisfactory results, these being arranged in somewhat elaborate tabular form. Complete insensibility was obtained in male patients in 12· minutes, and in females in 9·7 minutes, taking the average of all the cases. In four females the time required was less than five minutes. In thirty females and ten males five minutes was sufficient. No female required more than twenty-five minutes, but three males required half an hour and one forty minutes. The maximum quantity used to obtain complete anæsthesia was 5 drachms for males and 3½ drachms for females. They were all adults with the exception of seven boys and eleven girls under fifteen years of age. The average quantity of chloroform used in producing complete anæsthesia was for males 2·24 drachms, and for females 1·64 drachms, calculating the fluid drachm as marked on the bottle as equal to 5·3 grammes, instead of Dr. Soloveischik's figure, which is evidently based on the assumption that the marked drachms are equivalent to Russian drachms by weight. The mean quantity used per minute during complete anæsthesia

Hosted by Google

was found to be 0·54 gramme, which compares very favourably with the figures given by Gurlt,[1] according to whom when Esmarch's mask is used a gramme of chloroform is required per minute, and when Kappeler's apparatus is employed 0·6 gramme. In one case (empyema) cessation of respiration occurred after only half a drachm had been given. In another case the excitement was so great that after twenty-five minutes, during which half an ounce had been given, Esmarch's mask was substituted for Kappeler's. After ten minutes' further administration breathing ceased, and artificial respiration was resorted to with a successful result. In four cases only was there any vomiting, and in these only towards the end of the operation.

M. HAFFKINE.

OUR readers are well acquainted with the enthusiastic spirit in which M. Haffkine has carried on his labours in India while endeavouring to deal with such diseases as cholera and bubonic plague. We are glad, therefore, to be able to congratulate him on the fact that the Government of India, recognising the arduous and valuable nature of his recent work in connexion with the plague, have sanctioned the grant of a monthly salary of Rs. 2000 to him instead of the allowances hitherto given. This arrangement is to have a retrospective effect from the date on which he began work in Bombay.

VOICE-TRAINING.

THE Society for Physical Voice-training has received favourable notice in the *Cambridge Review* for April 29th. Our contemporary asks, "Why should we not have a professor of rhetoric?" We do not think the present a very good opportunity for the suggestion of new professorships or readerships at Cambridge, having regard to the admitted poverty of the University, but we certainly think that the proper cultivation of the voice is a subject upon which all educational bodies would do well to take thought. Every educated man ought to be able to speak and read aloud in a way that is comprehensible, and not only comprehensible but pleasant, to his hearers, but as a matter of fact the ordinary Englishman can do neither the one nor the other.

"CHURCHED TWICE IN ONE WEEK."

OUR attention has been directed to a paragraph in the *Manx Church Magazine* for January, 1893. An extract from a parish register dated 1630 is there given as follows: "1660. Rob Cottier's wife was delivered of a child which was baptised upon the Monday and she came to the church to be churched upon the Wednesday next after, and after returning home she fell in labour and was delivered of another child, and came to be churched upon the Saturday next after in the same week. Churched twice in one week. This I certify to be the truth.—Edward Crow, minister." It will be seen that the exact interval between the two confinements is not given. For all the register directly says to the contrary, the child whose baptism is mentioned might have been a year old, or even a person "of riper years"; the first churching might, also, have been left somewhat in arrear; but evidently the probability is that Edward Crow was somewhat struck with the fact that after the birth of a mature, or premature, infant a woman, without renewed coitus, may in the course of one, two, or three months give birth to another child, which may be mature or premature. There are three classes of such cases. In twin pregnancies after one child is born the other may be retained some weeks or months and then be born; again, a woman may have a double uterus, in each side there may be an ovum, and each side may expel its fœtus at a different time; lastly, it may be a genuine case of superfœtation. Coitus taking place in the early months of pregnancy, a second ovum may be fertilised, and the children be born at different times. A case recorded by Dr. Bonnar, quoted in Playfair's Midwifery, is a good example of this class. A child was born on Sept. 12th, 1849, and another on Jan. 24th, 1850—that is, about sixteen weeks after the first. Both children survived, so that the second child could not have been conceived after the birth of the first, or we should find a fœtus of about sixteen weeks' development born alive and surviving, which is impossible. On the other hand, the case could not be one of twins, the first of which was expelled prematurely, because the first born who survived would be, on that hypothesis, of only about five months' development.

[1] Archiv für Klinische Chirurgie, 1891 and 1893.

FORTY YEARS OF OFFICE.

MR. SAMUEL STRETTON of Kidderminster has resigned his appointment as medical officer to the workhouse after forty years' service. Forty years is a very large slice out of a man's active life—it is, in fact, a longer time of working activity than the average medical man enjoys—but during all this period Mr. Stretton has devoted himself with enthusiasm to the care of the sick and aged poor of Kidderminster. Familiarity with the duties did not make him weary of them, so that we cannot be surprised that the guardians have received his resignation with outspoken regret, attributing to him the present excellent sanitary condition of their workhouse. We congratulate Mr. Stretton upon the reputation which he has thus won among his fellow townsmen for intelligent and kindly work.

THE RESOURCES OF CAMBRIDGE UNIVERSITY.

DR. BUTLER, the Master of Trinity, has written to the *Times* concerning the pecuniary position of Cambridge University. The precariousness of this position was pointed out in our columns some weeks ago[1] in an article founded upon a circular letter addressed to the press by the Duke of Devonshire, the Chancellor of the University. His Grace's letter concluded, it may be remembered, with the statement that "the re-endowment of the University in respect of many of its departments is a pressing necessity," while Dr. Butler's letter shows that in many of our great public schools practical re-endowment has taken place during the past sixty or seventy years, so that the ancient University has fallen behind the institutions whence she derives a large proportion of her raw material. In fact, the raw material reaches the University in a condition of elaboration almost higher than the University can maintain it at without sacrifices on the part of the executive and all concerned with the administration that should not be expected and cannot be continued. And even so the fall behind has been hardly prevented. This fact comes home to medical graduates more than to any section of the University, as it is in different departments of natural philosophy that an enormous increase of work has been coincident with an equal depreciation in income. One of the most remarkable features connected with the history of the University has been the rapid development of the medical school and the ancillary schools of anatomy and physiology, and now that it has become apparent under what grave pecuniary stress so much admirable work has been accomplished we are certain that the medical profession, whether connected with the University or not, will see that Cambridge has justified beforehand and fully any claim that it may make upon the public for relief. The medical profession may well bring their influence to bear on the public mind in favour of a generous response, should the letters of the Duke

[1] THE LANCET, April 24th, 1897.

Hosted by Google

of Devonshire and Dr. Butler be followed in the near future by any sort of appeal.

THE ILLNESS OF THE DUCHESS OF TECK.

THE Duchess of Teck's illness has caused widespread anxiety proportional to her extreme personal popularity. We are glad to be able to inform our readers that Her Royal Highness, upon whom an operation was performed on Friday evening, April 30th, by Mr. Herbert W. Allingham, after consultation with Mr. T. Smith and Dr. Wadd, has since progressed favourably.

ALCOHOLIC PARALYSIS IN A CHILD.

AN account of a very interesting and important case was published some months ago in the *New York Medical Journal* by Dr. Herter. The patient was a child, aged three years, who had taken twelve ounces of whisky, and who very soon after lapsed into a condition of stupor which lasted, with variations, for a couple of months. Frequent convulsions occurred during this time, usually general, but occasionally restricted to the left side. Paralysis of the right side also developed, affecting the arm more than the leg, and contractures took place with muscular atrophy and loss of Faradaic excitability in the muscles. There were also strabismus, occasional sickness, and irregular temperature, due to the development of a slow lobar pneumonia. After an illness lasting about four months complete recovery took place. The case is very interesting on account of its unusual character and the many cerebral symptoms suggesting meningitis which developed, and Dr. Herber is to be congratulated upon his success in the diagnosis and also in the treatment of the condition.

THE CAUSATION OF INSANITY.

THE *Times* of Saturday, May 1st, in alluding to the Holloway Sanatorium, contains the following remarks based upon the annual report of the medical superintendent, Dr. S. Rees Philipps: "Worry was, as usual, the most potent cause of insanity; alcoholic intemperance played a very secondary part. Dr. Clouston, of the Morningside Asylum, Edinburgh, had convinced himself that more insanity was due to alcohol than any other cause. Dr. Philipps' observations tended to show that in England alcoholic intemperance was as often a result as a cause of insanity." These are startling assertions, and the opinions here expressed are undoubtedly opposed to the views held by most alienists. The term "worry" is evidently used in a very comprehensive sense, and seemingly embraces nearly all the causes of insanity denominated "moral" in the tables of the Medico-Psychological Association. Regarded from this standpoint alcohol may rank as a less important cause, but it is generally believed that alcohol and heredity bulk very largely in the causation of insanity. The view that alcoholic intemperance is as often a result as a cause of mental disease will not, we think, meet with much support.

MEDICAL MEN AND HOSPITAL BOARDS OF MANAGEMENT.

THE power for good which may be exercised by timely action on the part of a hospital staff has received practical illustration at Huddersfield. Although the accommodation of the infirmary there has been for some time inadequate, and even behind the times, there was a disposition on the part of the town to overlook its claims to share in any scheme for celebrating the Queen's Diamond Jubilee. Jealous of the welfare, and alive to the needs, of their infirmary the members of the honorary staff addressed a cogent but temperate letter to the local press in support of the infirmary's claim to recognition. But, although the commemoration of Her Majesty's reign was the ground for the response to this appeal, it came not from the townspeople as a whole, but from Mr. Hildred Carlile, who has sent a cheque for £8000 to the President of the infirmary. With this munificent donation the board has now a sufficient sum in hand to allow the additions to, and alterations of, the infirmary to be carried out forthwith. We congratulate the medical staff on the share they have had in conducing to this happy result. The munificence of the generous donor should live long in the hearts of those in the district which this infirmary serves, and other hospital boards may learn the lesson that they will be gainers by closely cementing their relations with the members of their staffs, and by giving them a share and voice in the management of their hospitals with a more generous hand than is sometimes done. The services rendered by hospital physicians and surgeons in their professional capacity surely entitle them to seats on the boards of management, whilst a staff working harmoniously with the lay managers may exert an influence and conduce to such a result as that which is announced at Huddersfield.

A CHINESE ENVOY IN QUARANTINE.

INFORMATION reaches us to the effect that amongst the passengers of the mail steamer *Empress of China* is Chang Yui Huan, the Special Envoy of the Emperor of China to the Diamond Jubilee celebration, and that the steamship is in quarantine at Victoria, British Columbia, on account of small-pox having occurred on board. The envoy protests against the imposition of quarantine upon one who is not under the control of the Colonial Government or the local authority, and he is stated to have forwarded his protest both to Lord Salisbury and to the Emperor of China. We rather doubt whether the envoy has any real remedy as to this. Vessels belonging to foreign Governments, such as men-of-war and transports, are generally exempt from the control of local authorities, but if the vessel is not one of this class, and it goes to a country where quarantine restrictions are applied, we know of no exception as regards individuals on board. Then, again, it is said that the envoy objects to having to undergo disinfection, and that he has announced that he will resist it by force. We hope, for the sake of the Colonial authorities, that no proposal has been made to disinfect an individual who is not actually suffering from disease. The disinfection of individuals is a thing of the past, and has no meaning in the light of modern scientific methods, except, for example, when a convalescent from such a disease as scarlet fever takes baths to rid his skin of desquamating epithelium. The story altogether savours of a past generation and much of it may admit of being explained away.

WE regret to learn of the death, at the age of sixty-five years, of Dr. H. Vandyke Carter, honorary surgeon to the Queen and Deputy Surgeon-General of the Indian Medical Service, which took place on May 4th at Scarborough. Dr. Carter's contributions to pathology and medicine are widely known, especially in such subjects as urinary calculi, relapsing fever, leprosy, and parasitic skin diseases. His researches on mycetoma threw considerable light on the nature of a disease which has since been closely identified with actinomycosis.

THE tenth annual Cookery and Food Exhibition will be opened at Niagara Hall, St. James's-park, S.W., on May 12th, by the Right Hon. the Baroness Burdett-Coutts, accompanied by Lord and Lady Methuen.

THE Conversazione of the Medical Society of London will be held on May 17th in the society's rooms, 11, Chandos-street, at 8.30 P.M. Mr. Edmund Owen will deliver the Oration.

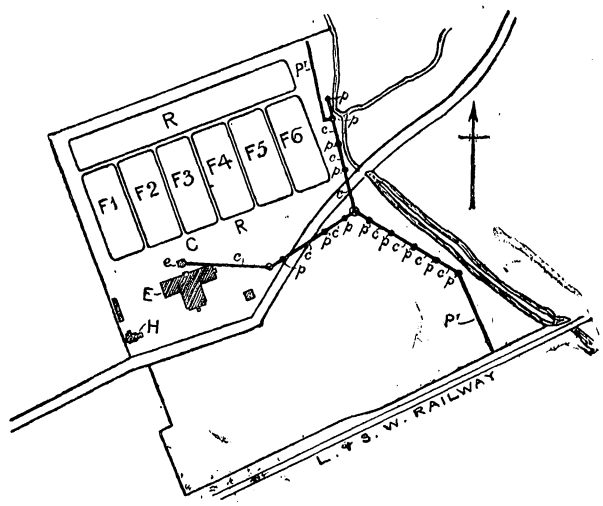
The Lancet Special Commission
ON THE
METROPOLITAN WATER-SUPPLY.

XI.[1]

EAST LONDON WATERWORKS COMPANY (*Continued*).

Present State.—General Condition.

THE East London Waterworks Company supplies Shoreditch, Haggerston, Stepney, Limehouse, the Isle of Dogs, Bow, Bromley, Homerton, Stratford, East and West Ham, the Victoria and Albert Docks, Leytonstone, Wanstead, Woodford, Buckhurst-hill, High Beach, Waltham Abbey, Chingford, and Walthamstow. The area of supply is situated immediately to the east of that of the New River Company. The sources of supply are (1) the Thames near Sunbury; (2) gravel beds in the parish of Sunbury; (3) the River Lea; and (4) deep wells at Waltham Abbey, Chingford, Walthamstow, and Lea Bridge. The stations of the Company indicated on the map are A, Sunbury (intake and pumping-station); B, Hanworth (reservoirs, filter beds, pumping-station, and arrangements for collecting water from the gravel); C, Hornsey Wood (reservoir); D, Waltham Abbey (well and pumping station); G, Chingford (well and pumping station); H, High Beach (reservoir); I, Buckhurst Hill (reservoir); J, Hagger Lane (reservoir); K, Walthamstow (reservoir, well, and pumping station); and L, Lea Bridge (well, pumping station, and filter beds). There are also three wells under construction. Of these stations two are situated in the valley of the Thames, far away from the others. The remaining stations are situated in the valley of the Lea, in the district supplied by the Company. The Thames stations are Sunbury and Hanworth.



Sunbury (see A on Map).—The station at Sunbury consists of an intake from the Thames and pumping machinery to force the water to the station at Hanworth. The intake from the Thames is situated on the Wheatley's Eyot. This island is in the parish of Walton-on-Thames, in the county of Surrey, but is situated much nearer to the Middlesex bank of the river than to the Surrey bank. The stream which divides it from the Middlesex bank is only twenty-one yards across, and the great bulk of the water of the Thames passes between the island and the Surrey side. The height of the water at the point of intake is 28 ft. above ordnance datum. The East London is the only metropolitan company which takes water from the Thames above Sunbury lock. The intake is 20 ft. in width and 10 ft. in depth. It is guarded by a grating formed of iron bars, 1¼ in. square, placed anglewise. The spaces between the bars are about ⅞ in. in width. These bars form the only screen through which the water passes; there is no wire netting at the intake. From the point at which the water is taken from the Thames three brick culverts pass to the backwater which divides the island from the mainland. The water is conducted under the backwater by three 48 in. iron mains to the mainland. From the bank the water is conducted through three brick culverts into an oval well 18 ft. in length and 12 ft. in width. From the well two egg-shaped culverts pass to the engine wells.

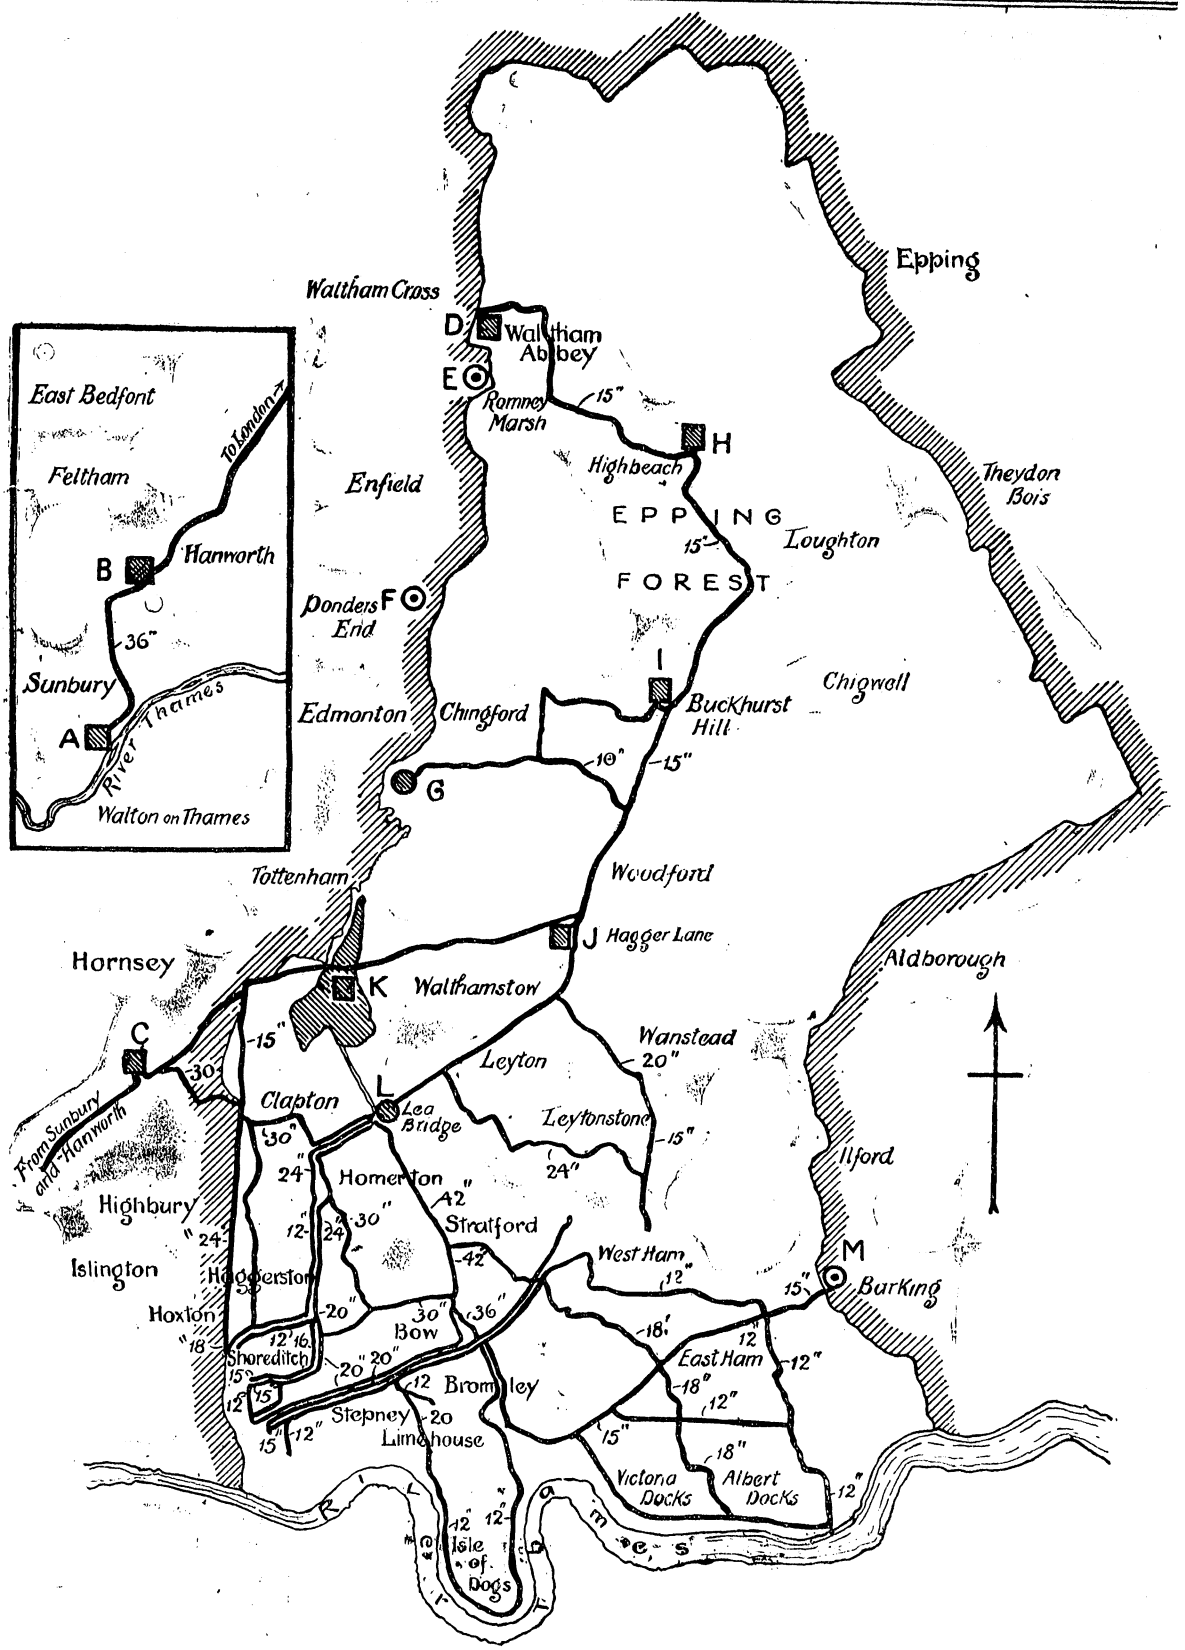
Engine-house.—The engine-house is built of brick. The water is pumped by two single acting Bull engines with 54 in. cylinders, which work plunger pumps of which the diameters are 45 in. and the stroke 9 ft. Steam is generated by four Cornish boilers, which work at a pressure of forty pounds. The water is pumped to the reservoir at Hanworth, a distance of about two miles, through a 36 in. main, which passes along the main roads. At this station there is a stand-pipe 40 ft. in height. When the works were first started here the water was pumped to a cistern 12 ft. in diameter and 20 ft. in depth, which was placed in a water tower, and from this cistern the water flowed by gravitation to the reservoir at Hanworth. The present arrangement is that the water is pumped direct to Hanworth and a stand-pipe is used to equalise the pressure, acting as an air valve. A cottage for a caretaker is situated at this station.

Hanworth (See B on Map and Fig. 1).—The station at Hanworth is situated in the parish of Sunbury, on the borders of the parish of Hanworth. It is called the Hanworth Station by the East London Waterworks Company to distinguish it from the one on the banks of the river at Sunbury which has been just described. The station at Hanworth consists of a reservoir, filter beds, pumping arrangements, and a system of underground works used for collecting water from the sand.

Reservoir (see Fig. 1, R).—The reservoir is 775 ft. in length and 116 ft. in width. The bottom and sides of the reservoir are cemented and the sides lined with brick. The sides are not vertical, but slope slightly (1 to 4). The reservoir has an available capacity of 5,000,000 gallons. It is supplied from Sunbury with unfiltered Thames water, and the water passes from it to the filter-beds.

FIG. 1.

Hanworth station. R, Reservoir. F 1 to F 6, Filter beds. C R, Covered reservoir. E, Engine-house. H, Engineer's house. P', Perforated pipes for the collection of gravel water. *p p*, Perforated iron piles. *c c c*, Culvert. *e*, Engine-house for pump taking gravel water to C R.



Filter beds (see Fig. 1, F 1 to F 6).—There are six filter beds, which have a total area of five acres. The sides are built of concrete and faced with brick. The composition of the filter beds is as follows. At the bottom a layer of 12 in. of large stones is placed, next a layer of 6 in. of hoggin—that is to say, small stones about the size of peas—above this is a layer of sand 2 ft. 3 in. in depth, when the filter bed is first made. When the sand is scraped off for cleansing purposes the thickness is gradually diminished until the layer of sand is about 1 ft. 9 in. in thickness. The floor of the filter bed slopes slightly towards the culvert, which is placed in the centre. The culvert is of circular form, 3 ft. in diameter, and has a row of perforated bricks level with the floor of the filter. Through these perforations the filtered water passes.

Cleansing filter beds.—As a rule, one filter bed is cleansed each week, so that on an average each filter bed in use is cleansed once in six weeks, or, to put it differently, a filter is allowed to work for about five weeks. During the early summer, however, it is necessary to cleanse the filters much more frequently. There is at this time always a great and rapid growth of weeds, which block the filters, and this makes it necessary that they should be cleansed at the end of a fortnight, or even at the end of a week. The sand is washed by a stream of water from the main at a pressure of about 10 ft. The water which has been used for washing the sand passes to a small pond on the outskirts of the property, where, after it has been allowed to stand in order to deposit its impurities by sedimentation, it passes into a neighbouring ditch.

Underground water.—The arrangements for the collection

[1] Nos. I., II., III., IV., V., VI., VII., VIII., IX., and X. were published in THE LANCET of Feb. 20th and 27th, March 6th, 13th, 20th, and 27th, April 3rd, 17th, 24th, and May 1st, 1897, respectively.

THE EAST LONDON WATERWORKS COMPANY.

The shaded outline with the northern bank of the river defines the area supplied by the Company. Wells are marked as shaded circles, reservoirs are marked as shaded squares. The dark lines show the course of the principal mains, the diameters being marked in inches. A, Sunbury, intake and pumping station. B, Hanworth, reservoirs, filter beds, pumping stations, and arrangements for collecting water from the gravel (see Fig. 1). C, Hornsey Wood, reservoir. D, Waltham Abbey, well and pumping station. G, Chingford, well and pumping station. H, High Beech, reservoir. I, Buckhurst Hill, reservoir. J, Hagger Lane, reservoir. K, Walthamstow, reservoir, well, and pumping station. L, Lea Bridge, well, pumping station, and filter beds. E, F, and M, three wells under construction.

Hosted by Google

of underground water at Hanworth station differs from the arrangements which have been described as existing at the stations of the Chelsea and Southwark and Vauxhall Companies (see articles III. and V.). It may be best to go into some little detail as to the manner in which the underground water is collected, because, as far as we know, the arrangement here adopted does not exist elsewhere, or, at any rate, it was first carried out here, and was invented by the engineer of the East London Waterworks Company. It will be necessary for the sake of clearness to briefly describe the conditions of the ground here met with in order to explain how it is that the arrangements made are the best that could have been adopted. The story of the origin of the works is briefly as follows. When excavations were made at this station it was found that under 3 ft. of alluvial soil there was a layer of gravel about 18 ft. in thickness. The lower part of this gravel was full of water, which, indeed, gave a good deal of trouble when the original works were being carried out here. It seemed to the engineer of the company that it would be worth while to find out whether this water was of good quality for drinking. It proved to be of good quality, and it was therefore determined to collect it. The fact that the lower layers of gravel were filled with water would have caused a good deal of trouble in laying pipes in the ordinary way, because it would, of course have been necessary to keep the water pumped whilst the excavations were in progress. The impervious nature of the underlying London clay suggested the advisability of making use of this quality by making a culvert in it for the purpose of conducting the water from the overlying gravel to a central well. In order to carry out this idea the method adopted was as follows. A number of hollow iron piles with perforations in the sides were driven from the surface of the ground right down into the London clay, so that only about 2 ft. or so of the pile remained projecting above the ground, and a length of 38 ft. was under the ground. A number of these piles were driven in at regular intervals in straight lines in the direction of a well which had been already sunk (see Fig. 1, *p p p*). The well was then pumped dry and a culvert was dug in the London clay in the line of the piles, so that the lower part of the piles projected into the culvert (see Fig. 1, *c c c*). The condition of things which obtained then was that from the surface of the ground to the culvert hollow iron piles passed, and the lower parts of the piles which projected into the culvert were filled with London clay, which they had met with as they were driven down into the culvert—that is to say, the lower part of each pipe was plugged with a layer of London clay. This clay being removed from below the water was then able to flow from the saturated layer of gravel down into the culvert. The culvert led to a well in an engine-house (see Fig. 1, *e*.), from which it was afterwards pumped to the covered reservoir (Fig. 1, CR). By an arrangement of valves the water contained in each pile can be prevented from passing into the culvert below, and then after the water has been pumped out from the culvert its whole length can be explored. The perforated iron piles which collect the water from the gravel and conduct it to the culvert, which is situated in the clay beneath, were constructed for the purpose which they subserve. The arrangements are simple, ingenious, and carry out perfectly the intention for which they were made. There are altogether about twenty of these iron piles.

Small engine-house (see Fig. 1, *e*).—Another engine-house contains two compound surface condensing centrifugal engines of about 20 horse-power each. These are used for pumping the gravel water into the reservoir.

Covered reservoir (see Fig. 1, C R).—There is a reservoir covered with brick arches and capable of holding 2,500,000 gallons. Into this reservoir the filtered water gravitates and the water from the gravel beds is pumped, and from it the water is pumped to Finsbury-park.

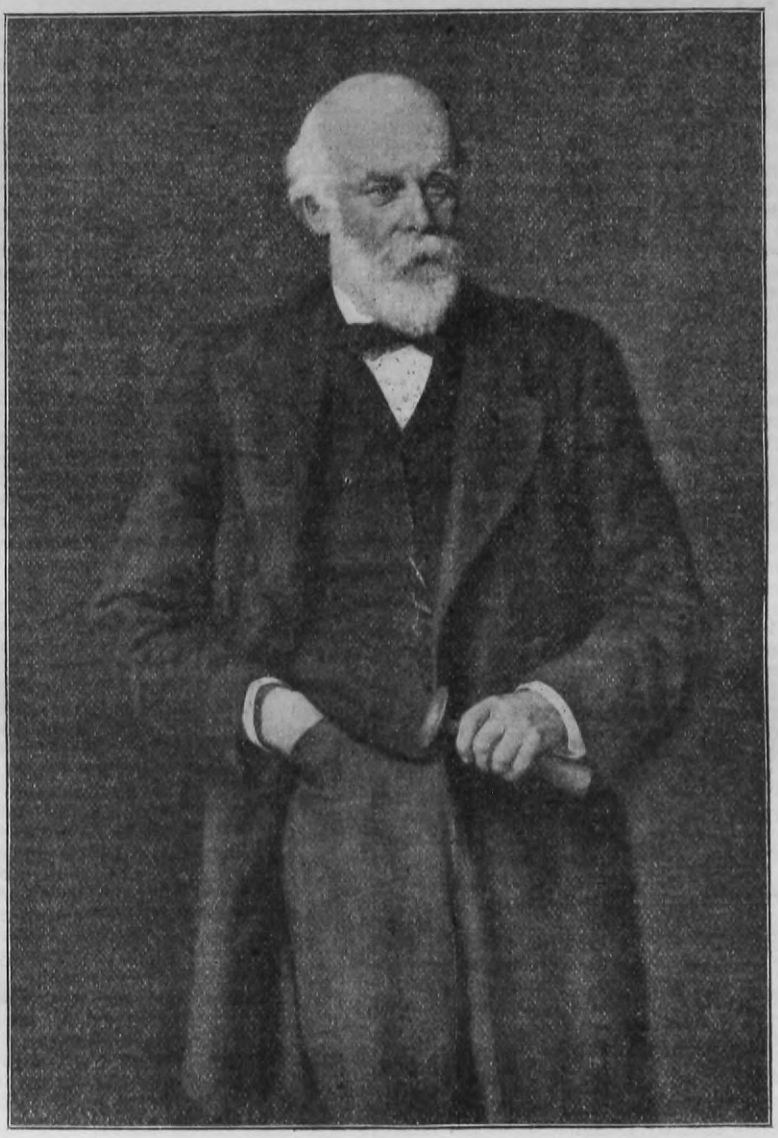
Engine-house (see Fig. 1, E).—The water from the covered reservoir is pumped by three Cornish beam engines, having cylinders 84 in. in diameter and a stroke of 11 ft., working plunger pumps 36 in. in diameter, and having a stroke of 9 ft. The steam is generated by ten Cornish boilers, working at a pressure of 40 pounds. These engines pump filtered water and water from the gravel to the reservoir in Finsbury-park, a distance of about nineteen miles. The main through which the water passes is 36 in. in diameter.

(To be continued.)

THE BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

A CONVERSAZIONE was given by the members of this comparatively new but fast-growing society at Limmer's Hotel, Conduit-street, London, W., on April 28th. An exhibition of drugs, meteorological instruments, and photographs of balneo-therapeutical appliances was greatly appreciated by those present. The attractions of the evening were enhanced by the music supplied by the Blue Zouave Ladies' Orchestra.

Previously to the reception by the President (Mr. Andrew S. Myrtle, M.D. Edin., J.P., of Harrogate), Sir DOUGLAS POWELL delivered an interesting address, which took the form of an extremely entertaining *résumé* of the progress of climato- and balneo-therapeutics during the past few years. Speaking of the origin of the society he said he believed that it was founded in response to a wish or feeling which originated from a Committee of the Royal Medical and Chirurgical Society in 1889, under the presidency of Sir Edward Sieveking. The efforts of that committee were very successful in bringing forward most valuable information with respect to the climatic and balneo-therapeutic resources of the British Isles. He congratulated the British Balneological and Climatological Society upon its growth and upon the fact that its roll contained the names of some of the best-known members of the profession. It was an additional matter for congratulation, he thought, that the society numbered among its members, not only those who were strictly concerned with climato- or balneo-therapeutic work, but also those who, like himself, had no special knowledge of climate or baths except such as was derived from experience or research. Sir Douglas Powell referred to the importance of making a correct diagnosis of a case before it was sent to a spa, although it might often happen that a case was sent to a bath in a state of what he called suspended or tentative diagnosis, with a view to its being carefully watched for a time under treatment at the bath. Speaking of the exercise treatment of cardiac diseases he said that discredit had been brought upon the method by reason of many cases being treated too severely; many cases sent to baths were not in a condition for such treatment. The Schott treatment, too, had been of immense value in a small minority of carefully selected cases, but even this treatment from the very publicity which it had acquired was, he ventured to say, rapidly losing ground. He hoped it would be one of the functions of this society to have a controlling influence in this matter. Whilst the movement and bath treatment of cardiac disease had been carefully organised of late years, insufficient attention, he thought, had been given to the rest treatment in that and other diseases. At all events, such cases as anæmia, cardiac affections in the early and ingravescent stages, and pulmonary affections in the acute and ingravescent cases benefit by a very rigid degree of rest treatment. Much might be done, he said, to improve our health resorts—our southern ones more particularly—with regard to this treatment. What was wanted was more "sun-traps," more balconies with glass screens which would not obstruct the light, but which would protect the patients from winds, and open spaces where the patients might be exposed to the sunshine and sheltered from the inclemency of the weather. He instanced the Madeira-walk at Brighton as a most valuable example that might be followed by other health resorts. Frequently placed sheltered rests were also required. In these sort of things we were outdone by foreign health resorts, which were not to be compared with our own at certain times of the year.



H.R.H. THE DUCHESS OF ALBANY will open the new Convalescent Home of the National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen-square, on Wednesday, June 16th. The home is at East Finchley, and has been provided for a class of patients inadmissible to every other convalescent institution in the kingdom. Only a small balance of the cost remains to be collected, and the board hope to be privileged to inform Her Royal Highness that the home is opened free from debt.

Obituary.

JAMES ANDREW, M.D. OXON., F.R.C.P. LOND.

ON April 21st, at Tavistock, James Andrew entered into a well-earned rest, aged sixty-seven years. He was born at Whitby, of which place his father was for thirty-four years perpetual curate. He was the youngest of three sons, and had one sister. His early education was partly at the hands of his father and partly from the rector of Glaisdale, the Rev. B Richardson; thence he went to Sedbergh, and thence he matriculated at Worcester College, Oxford, taking his M.B. degree in 1860, and proceeding to that of Doctor in 1863 He was Fellow and Tutor of Wadham College, and was about to proceed to Paris when an opening presenting itself at St. Bartholomew's Hospital he applied for and obtained the appointment of Demonstrator of Morbid Anatomy. This post he held until January, 1867. From 1861 to 1865 he was a warden of the college at the hospital. He was elected assistant physician in 1864, and joint lecturer on medicine the same year, which post he held until 1890. In 1869 he was made full physician, an office he continued to hold until 1893, when he was appointed consulting physician. On his resignation as physician he was presented by his friends with his portrait and among other things a tricycle. In 1890 he suffered very severely from influenza, and although he recovered to a certain extent his health was never the same, and in 1895 he began to fail very fast, eventually dying, as stated above, at Tavistock. On April 24th he was buried at Peter Tavy.

James Andrew was a man not much known out of the ranks of his immediate friends and acquaintances, for he was of a very shy and retiring disposition; but those who had the honour of his friendship—and it was a great honour—knew what sterling worth there was in the man and what a lovable character his was. He was an admirable specimen of that now almost extinct species, the old-fashioned Oxford man, a good scholar and a man of thoroughly cultured mind. He was always ready to assist those in need with either advice or money, and took many a long journey to bring his skill to bear upon cases without getting anything like a fair remuneration. His lectures were instructive, full of sound sense and really helpful, though not perhaps models of oratory. He wrote but little, his chief works being his thesis on the Relation of Anasarca to Renal Disease in Acute Albuminuria, the Diagnosis of Systolic Murmurs at the Heart's Apex, a paper on Disease of the Mitral Valve, and his Lumleian Lectures on the Etiology of Phthisis. Though old-fashioned, he was an absolutely sound and excellent physician, and his kindness and thoughtfulness for his hospital patients was a thing never to be forgotten by those who saw them. His treatment was in the best sense scientific, and his favourite answer to the question of students, "What is the best book on Medicine?" was "Foster's Physiology" — an answer which showed the cast of his mind, and was well illustrated by his Harveian Oration delivered in 1890. He was a keen observer, an ardent dialectician, very fond of the Socratic method of answering one question by another, and never ashamed to own that he had been wrong. No trouble was too great for him to take over a severe case, and he never spared himself in explaining matters to inquirers. For the following more personal reminiscences we are indebted to one who served under him at the hospital and knew him well.

"James Andrew was one of the most helpful and considerate men who ever breathed and as good a physician as London could produce. To all Oxford men his loss will be irreparable. All who had the privilege of being taught by him at those memorable evening meetings will remember

Hosted by Google

with affection the little bowed figure who met you at the door of 22, Harley-street, and who dived down the kitchen stairs with a quick movement irresistibly reminiscent of a rabbit, his old briar pipe, and his keen incisive talk upon medicine. No one could put things more clearly or make a subject more interesting, and no one laboured more earnestly to bring down his own intellect to the level of your comparatively dull one. Neither did he forget those whom he had known when they went out into the world, but always had a genial greeting and a kindly query as to their position and prospects. His great amusement was fishing, and he was a thoroughly good sportsman. These details may appear very trivial, but they are very characteristic of the man, and will serve to remind those, if any reminder is needed, who knew him of a very lovable personality."

The accompanying portrait we reproduce by permission of the authorities of St. Bartholomew's Hospital from the one which hangs in the great hall. It is an admirable likeness of the man and his little personal attributes. The old frock coat, with the pin stuck in the lapel and used for testing sensation and the odd-shaped stethoscope, are all part of his personality. And so we close this notice, imperfect at the best, of one who never attained the position he was worthy of, but whose memory will ever live in the minds of those who knew and were privileged to work with him in even the humblest capacity.

Dr. Andrew was married in 1867 to Isabella, daughter of Henry Simpson of Bagdale, who survives him, but he has left no children.

DEATHS OF EMINENT FOREIGN MEDICAL MEN. — The deaths of the following eminent medical men are announced:—Dr. Andreas Anagnostakis, who is described as the Nestor of Greek Ophthalmologists, at the age of seventy-one years. He was born in Crete, but his parents removed to Greece while he was a child, and he studied medicine in Athens and practised in a provincial town. In 1851 he obtained a scholarship from Queen Amalie, by means of which he was enabled to study in Paris and in Germany for five years. After his return he was appointed Professor of Ophthalmology in the University of Athens and inaugurated there an important school in which the teaching of Helmholtz, von Graefe, Donders, and others has been consistently carried out. Dr. Anagnostakis was for several years Rector of the University, where he was held in great respect.—Professor Gustave Braun, a well-known Moscow ophthalmic surgeon.—Dr. G. Limoncelli, *privat-docent* of Mental Diseases in the University of Naples.—Dr. Margitot, Member of the Paris Academy of Medicine.—Dr. Jaime Pi y Suñer, Professor of General Pathology in the Barcelona School of Medicine.—Dr. H. Engel, formerly Professor of Nervous Diseases in the Philadelphia Medico-Chirurgical College.—Dr. S. G. Moses, formerly Professor of Midwifery and Gynæcology in the Missouri Medical College, St. Louis.

ANNUAL REPORT OF THE SANITARY COMMISSIONER OF THE GOVERNMENT OF INDIA FOR 1895.

[CONCLUDING NOTICE.[1]]

IN our former notice of this report we referred to the changes which had been introduced at the suggestion and instigation of the Army Sanitary Commission, to the interesting data contrasting the past and present mortality of European soldiers in India contained in the volume under review, and to some of the epidemic diseases which had prevailed among the troops in 1895.

We learn that the admisssion and death-rates from dysentery were greatly, and those from diarrhœa somewhat, increased in that year, owing for the most part to service in the Chitral expedition. The highest percentage of admissions for abscess of the liver was on the Burma coast, but the highest percentage of deaths from hepatic abscess to total deaths was in Southern India. Speaking generally, groups of stations that had a high admission ratio from dysentery, had also a high admission rate from abscess of the liver, but they do not correspond very closely; 27 per cent., or 42 cases out of 154, were returned as associated with dysentery. Of the 51 fatal cases described with sufficient minuteness, we are told that 21 had a single abscess, and 30 multiple abscesses. There were 7 of the 21 single abscesses associated with dysentery or intestinal ulceration, and 14 not so associated; the thirty multiple abscesses, on the other hand, were associated with dysentery or intestinal ulceration in 21 cases, or 70 per cent., and not so associated in 9 cases, or 30 per cent. These points have an obviously important bearing on medical diagnosis and prognosis in regard to surgical procedure. The question of the causal importance of the amœba coli is still under discussion; but, on the whole, the majority of observers are convinced that there is an amœbic abscess of the liver as there is an amœbic dysentery. The brief remarks on this subject at page 45 of the report are worth reading. A table follows showing that the mortality from abscess of the liver in 1895 was more than seventy times greater among European than among native soldiers, while on the other hand, the admission ratio from dysentery among European soldiers was to that of the native soldiers as 1:1·4. This matter was more fully gone into in the report for 1894. It may be incidentally remarked that, while no cases of hepatic abscess following enteric fever were returned in 1895, there were several cases consequent on apparently non-dysenteric ulceration.

The next subject is one which has of late occupied a good deal of public attention; and no wonder, for the figures may be said to be, without exaggeration, appalling. The admission-rate for India for venereal disease was 522·3 in 1895, against 511·4 in the previous year, and the number of men constantly sick in hospital from venereal disease was equal to over three regiments. As youthful and recently arrived men have become more common in the army venereal disease and enteric fever have, not unnaturally we are told, increased in frequency of occurrence. From a tabular statement in the report we gather that there has been a more or less continuous rise in venereal disease and constitutional syphilis since 1885. But we need not stay to consider the subject further on this occasion, the statistical evidence and the proposed measures in regard to it having already given rise, as everyone knows, to much discussion. We may remark, however, that we do not attach so much importance as some do to ablution as a preventive measure. Practically, it is most difficult to ensure its being so promptly carried out as to be of use. Daily experience with solutions of cocaine, &c., in ophthalmic practice shows that absorption is very rapid. Turning to the vital statistics of officers we find that the death-rate for those of the British army was 11·10, and that for the Indian army 9·62, per 1000 respectively. Enteric fever, the Sanitary Commissioner remarks, caused more deaths among the British than among the Indian officers, apparently because the latter have to serve first with British regiments, and it is known that youthful and newly arrived men are more liable to take the disease than others. The invaliding rate, as might be expected, is much higher for officers than for men. The admission and death-rates from enteric fever among officers do not differ much from the corresponding ratio among the men, but the general admission and death-rates are lower among the former.

Passing on to that section of the report dealing with the native army of India we find several points of interest. Enteric fever is a well-known cause of great sickness and mortality among European troops in India, and the following table brings out the striking difference between the British and native armies and the gaol population of India in this respect.

—	1882-91.		1895.	
	Admissions.	Deaths.	Admissions.	Deaths.
European troops	14·7	4·13	26·3	6·72
Native troops	0·3	0·09	0·2	0·07
Prisoners	0·2	0·10	0·4	0·13

We have previously called attention to tables that have appeared in former reports to the same effect. About the fact, explain it how we may, there cannot be any doubt, for the figures are substantially repeated from year to year.

[1] The first notice appeared in THE LANCET, April 24th, 1897.

Hosted by Google

Among native prisoners nearly every fatal case of disease is subjected to post-mortem examination, although these rarely take place in the case of native soldiers. Moreover, the fever mortality in the European army is not the same in amount, which, as the Sanitary Commissioner observes, indicates that the difference is not a mere matter of diagnosis. Taking the percentages in deaths we find that 44·0 and 0·6 represent the mortality from enteric fever among European and native troops respectively. The amount of venereal disease among native troops is relatively small and remains pretty stationary. Native soldiers are usually married; they are abstainers from alcohol, have less pay than European soldiers, and remit much of it to their families; they belong to the country and do not commonly consort with the prostitute class, and would lose caste by doing so; and there has been no change in the native army corresponding to the introduction of the short service system in the British army. With regard to guinea-worm there are some interesting facts respecting the distribution of the parasite recorded in the report. The number of cases during the year amounted to 516, against 499 in 1894. By far the largest number of admissions occurred in South-Eastern Rajputana, Central India, and Gujarat. Of the total number of cases, 9 per cent. declared themselves at Kherwara and 6 per cent. at Sirdarpore. There were only 3 cases altogether in the whole European army. This great contrast is stated to be probably due to the different customs of Europeans and natives as regards bathing and water drinking.

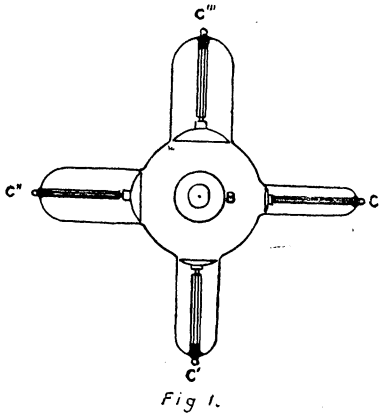
It would be extremely difficult to discuss the sections dealing with the gaol population and the history of the chief diseases among the general population in the limits of space at our disposal; and those of our readers interested in the subject, and in the history of cholera during the year under review, must turn to the report for themselves, in which the results of the various inquiries, and of the bacteriological investigations that were instituted by Mr. Hankin and others are given. Section X. deals with a number of subjects including a summary of the facts connected with the Red Sea pilgrim traffic and the outbreak of cholera at Camaran, the researches conducted in the biological laboratory attached to the office of the Sanitary Commissioner, and other matters.

In an appendix to the Report the new rules are published regarding the measures to be adopted on the outbreak of cholera amongst troops in India, which are the outcome of an inquiry into the subject by a committee specially appointed for the purpose. The revised rules received the sanction of the Government of India on Sept. 10th, 1896.

ADJUSTABLE X RAY FOCUS TUBES.

MR. A. A. C. SWINTON writes:—As all who have had occasion to use x rays for practical purposes are aware, the penetrative value of the x rays produced by any given Crookes's tube depends very largely upon the exact degree to which the tube has been exhausted. Further, as is well known, a tube originally exhausted to any particular vacuum is found in practice to alter its degree of vacuum with age and with use. With tubes of the Jackson focus type that have been well exhausted in the first instance, the vacuum usually increases the more the tube is used, particularly if sufficient power is employed to heat to redness the platinum anti-cathode. Indeed, it is not unusual for this increase of vacuum to be such that it is eventually found impossible to get any discharge to pass through the tube at all. Various arrangements have from time to time been suggested and tried for the purpose of regulating the vacuum in tubes. One plan is to keep the tube permanently attached to the mercury pump, so that a little air can be pumped out or a little let in whenever it is found necessary. Another arrangement is to place some material, as, for instance, caustic potash, which is capable of absorbing air and giving it out again when warmed, in a small pocket or annex to the tube, which can be heated by means of a spirit lamp and the vacuum reduced as occasion requires. This, however, as also the ordinary plan of heating the whole tube by means of a spirit lamp or Bunsen burner, so as to drive off into the interior of the bulb the gases condensed upon the glass, are at best only makeshift expedients, which, though capable of good effect in the hands of skilled experimenters, are not permanent in their results or adjustable with sufficient accuracy to be really satisfactory. Further, exceedingly minute alterations in vacuum will make all the difference between satisfactory and unsatisfactory results in some of the more difficult cases to which x rays are now applied. Under these circumstances I have devoted considerable attention to devising a method whereby the penetrative value of the x rays produced by a focus tube could be easily varied without alteration to the vacuum, and whereby, further, the penetrative value of the rays could be maintained constant at any desired degree, in spite of the uncontrollable variations in the vacuum that are found to occur in practice. The penetrative value of the rays for any given degree of vacuum depends, among other things, upon the area of the cathode disc and upon the lineal distance between the cathode and anti-cathode. Upon these principles I have designed two separate forms of adjustable focus tubes, Figs. 1 and 2 being two views of one of these tubes and Fig. 3 a view of the other.

In the form of tube shown in Figs. 1 and 2 advantage is taken of the difference of effect produced by employing



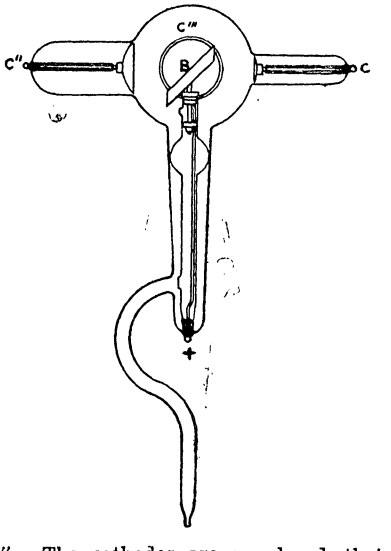


Fig 1.

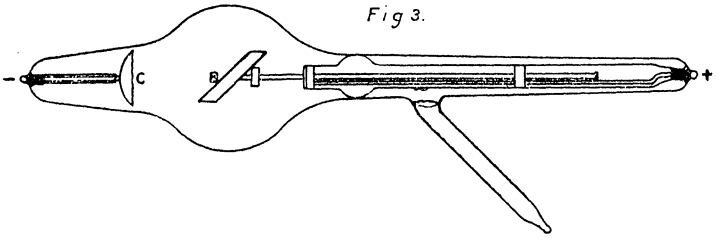
cathodes of various sizes. As will be seen from the illustration, the tube is provided with four concave aluminium cathodes, C, C′, C″, C‴, all of the same radius of curvature, namely, 0·75 inch, but of four different diameters, varying from 0·5 inch in the case of C, to 1·125 inches in the

Fig 2.

case of C‴. The cathodes are so placed that they all focus on a point in the centre of the bulb of the tube, and the inclined anti-cathode disc B is mounted upon a small steel spindle, turning in aluminium sockets, so that the anti-cathode can be easily rotated by tapping the tube, so as to face any one of the four cathodes that it is desired



Hosted by Google

to work with. The anti-cathode disc B, made of aluminium, is of considerable mass, being an oblique section about 0·25 inch in thickness, cut from an aluminium rod one inch in diameter. The cathode rays are not received direct upon the aluminium, but upon the surface of a disc of platinum about 0·6 inch in diameter, and about 0·025 in thickness, tightly wedged and riveted into a shallow circular depression turned out of the face of the aluminium block. The reason for the particular shape of the aluminium portion of the anti-cathode is to ensure its being balanced in all positions of the tube, so that it should have no tendency to rotate of itself. The object of the general arrangement is to prevent the platinum from attaining an excessive temperature, even when great electrical power is employed, this resulting from the considerable radiating surface of the aluminium, and its considerable mass requiring a long time to heat it up to any high degree. This arrangement makes the tubes take considerably longer to exhaust in the first instance, but renders them much more permanent, as not only is there no danger of melting the platinum, as frequently occurs in the ordinary form of anti-cathode, but also the difficulty experienced with the red-hot platinum occluding the residual gas, and thus increasing the vacuum, is largely done away with, while, in addition, the platinum having only one surface exposed and never getting very hot, the tubes do not blacken so quickly.

As will be seen from the illustration, the anti-cathode is supported in a long double glass tube, through which passes an aluminium connexion to the anode terminal. By this method great rigidity and accuracy are attainable and the anode and cathode terminals are kept well apart. During the process of exhaustion it is necessary to make each of the cathodes operative in turn so as to expel the residual gas, and finally the tube is exhausted to the necessary vacuum to produce x rays of medium penetrative value when one of the intermediate sized cathodes is in use. The tube is then sealed off, and afterwards the penetrative value of the rays can be varied at will by turning round the anti-cathode so as to face any one of the cathodes and making that cathode alone operative. The small cathode gives rays of the highest penetration and the large cathode rays of the lowest penetration. With cathodes of the dimensions given the range is very considerable. It can be diminished or increased by making the cathodes more nearly of one size or the reverse. In place of the rotating anti-cathode a fixed one may be used of four-sided pyramidical form with a platinum disc let in on each face opposite to each cathode. The anti-cathode terminal need not be used as anode, as when one disc is cathode the immediately opposite disc may be employed as anode.

The other tube, by which the penetrative value of the rays can be altered by quite a different method, is shown in Fig. 3. In this case the tube is fitted with but

Fig 3.

a single cathode C, and the anti-cathode B, which is of similar construction to that used in the other tube, is carried upon a steel rod, which slides in two aluminium blocks mounted in a glass tube and connected to the anode terminal. By slightly inclining and shaking the tube the anti-cathode can be made to slide along in the bulb so as to alter the distance between the cathode and the centre of the anti-cathode from about half an inch to three inches. Stops are provided upon the sliding steel rod to prevent its travelling too far in either direction. With a tube of this description it is found that the shorter the distance between the cathode and anti-cathode the higher is the penetrative value of the x rays, and *vice versâ;* so that by simply altering the position of the anti-cathode it is possible both to compensate for variations in vacuum, and also, within limits, to produce x rays of any desired penetrative value. I am indebted to the assistance of Mr. J. C. M. Stanton and Mr. H. L. Tyson Wolff, who made the tubes illustrated, as also all the earlier tubes with which the original experiments were carried out.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary meeting of the Comitia of the College was held on April 29th, Dr. WILKS, President, being in the chair.

The following gentlemen were admitted to the Membership of the College:—William Bain, M.D. Durh., F.R.C.S. Edin.; T. Hillier Chittenden, M.D. Durh.; Alfred Eddowes, M.D. Edin.; and E. S. Pasmore, M.D. Lond. The Licence of the College was granted to 108 gentlemen.

A communication was read from the secretary of the Royal College of Surgeons of England reporting certain proceedings of the Council of the College on April 8th.

The following Members of the College were elected Fellows:—J. A. Coutts, M.B. Camb.; J. Galloway, M.D. Aberd.; W. E. Wynter, M.D. Lond.; W. S. Colman, M.D. Lond.; A. F. Voelcker, M.D. Lond.; James Taylor, M.D. Edin.; G. I. Schorstein, M.B. Oxon.; E. H. Starling, M.D. Lond.; J. S. Risien Russell, M.D. Edin.; A. A. Kanthack, M.D. Lond.; J. R. Bradford, M.D. Lond.

The quarterly reports were received from the Finance Committee and from the Examiners for the College Licence.

A list of books presented to the library during the past quarter was received.

The names of Dr. Theodore Williams and Dr. Hood were added to the Finance Committee.

THE GRECO-TURKISH WAR.

THE latest news from Athens announces the fact that the Greeks are determined to continue the war. With the purely political or military aspects of the campaign we have, of course, but little concern. It is in the sanitary, medical, and ambulance transport arrangements of the belligerent forces that we are mainly interested, and as to these little or no reliable information has reached this country. The readers of the telegraphic reports from the seat of war and from Turkish and Greek sources are perplexed by their different and contradictory statements, but nothing that has occurred during the last few days seems likely to affect the real military situation. The fighting at Velestino may have been altogether, and for the time, in favour of the Greeks, but it does not essentially alter the position or annul the successful and highly important results which the Turkish troops under Edhem Pasha's command have already attained elsewhere. Turkish reinforcements are arriving, and unless there are any political reasons for Edhem Pasha's present inaction, it may be, and probably is the case, that the apparent delay on the part of the Turks is attributable to strategical reasons and to the fact that the Turkish plan of the campaign is not yet ripe, and the arrangements for any supreme or final effort on their part are not completed. Be this as it may, the number of killed and wounded in the engagements that have taken place does not seem to have been great when the strength of the belligerent armies is taken into account. As far as the scanty intelligence that has reached this country goes, the Turkish hospital service seems to be good; at any rate, nothing has been said to the contrary. The fortitude exhibited by the wounded Turks and the rapidity of their recovery have been remarked upon. The hospitals are stated to be well equipped and provided. As far as the Greeks are concerned, our readers have probably noticed that occasional references have been made by some of the war correspondents to the non-employment of chloroform and anæsthetics in their hospitals. Whether this be due to the fact that they have an insufficient supply of these among their hospital stores, or, what is most probably the case, that these agents are not generally used in minor cases of surgery, but reserved for all the major or more severe operations, we cannot say; but the accounts speak of the quiet fortitude and cheerfulness of the patients in the Greek military

Hosted by Google

hospitals, and references are made to the benevolent services of the nursing staff. We hear but little of the services of the Red Cross Society, although it is certain that its members must have been actively engaged in administering to the aid of the sick and wounded. A number of English and French surgeons from Constantinople are stated to be present with the Turkish force at Larissa. We suspect that, owing to the hilly and difficult nature of the country, there must have been unusual difficulty in getting field hospitals, or sections of field hospitals, well to the front in the fighting that has taken place hitherto.

BUBONIC PLAGUE IN INDIA.

THE Anglo-Indian papers by the last mail are still very full of this subject, but their general purport is favourable. The worst is over and the epidemic is still declining.

The Secretary of State for India has received the following telegram from the Governor of Bombay on the subject of the plague:—

"Deaths from all causes in Bombay city for week ended April 30th, 683; reported plague deaths, 169. The population is returning continuously and is now variously estimated at from 600,000 to 700,000. All persons coming into Bombay are now medically examined. In Poona city deaths from all causes during the week ended April 30th, 78; reported plague deaths, 45. Further inquiry confirms correctness of figures. Satisfactory result of Poona city operations shown by return of plague cases. They were: for week ended March 26th, 319; April 2nd, 238; April 9th, 235; April 16th, 159; April 23rd, 94; April 30th, 60."

At an adjourned meeting of the Bombay Medical and Physical Society, held on March 19th last, the papers read before the society on the subject of the plague on March 5th were discussed. A large diagrammatic chart has been prepared by Dr. Weir showing the progressive development of the epidemic, and the close relation between the total mortality and the mortality from plague, and the state of the barometer and dew-point during the prevalence of the disease.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6987 births and 3854 deaths were registered during the week ending May 1st. The annual rate of mortality in these towns, which had been 17·9 and 18·8 per 1000 in the two preceding weeks, declined again last week to 18·3. In London the rate was 16·8 per 1000, while it averaged 19·3 in the thirty-two provincial towns. The lowest rates in these towns were 9·9 in West Ham, 12·5 in Brighton, 12·8 in Plymouth, and 12·9 in Croydon; the highest rates were 25·2 in Manchester, 27·8 in Blackburn, 28·3 in Bolton, and 28·9 in Salford. The 3854 deaths included 351 which were referred to the principal zymotic diseases, against 334 and 367 in the two preceding weeks; of these, 110 resulted from measles, 104 from whooping-cough, 55 from diphtheria, 32 from scarlet fever, 31 from diarrhœa, and 19 from "fever" (principally enteric). No fatal case of any of these diseases occurred last week in Brighton or in Halifax; in the other towns they caused the lowest death-rates in Sunderland, Swansea, Derby, and Huddersfield, and the highest rates in Manchester, Burnley, Salford, and Bolton. The greatest mortality from measles occurred in Birkenhead, Liverpool, Bolton, Manchester, Salford, and Burnley; and from whooping-cough in Manchester, Burnley, and Blackburn. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 55 deaths from diphtheria included 40 in London, and 2 each in West Ham, Birmingham, Sheffield, and Hull. No fatal case of small-pox was registered in any of the thirty-three large towns. There were 12 cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, the 1st inst., against 16, 11, and 7 at the end of the three preceding weeks; 6 new cases were admitted during the week, against 1 and 0 in the two preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2380, against 2449, 2406, and 2442 on the three preceding Saturdays; 223 new cases were admitted during the week, against 234, 216, and 269 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 273 and 289 in the two preceding weeks, declined again to 273 last week, and were 91 below the corrected average. The causes of 43, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leicester, Nottingham, Bradford, Leeds, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Wolverhampton, Norwich, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·3 and 22·6 per 1000 in the two preceding weeks, declined again to 22·0 during the week ending May 1st, but exceeded by 3·7 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·9 in Dundee and 18·8 in Aberdeen to 25·6 in Perth and 30·1 in Edinburgh. The 655 deaths in these towns included 52 which were referred to measles, 45 to whooping-cough, 15 to diarrhœa, 6 to "fever," 6 to diphtheria, and 3 to scarlet fever. In all, 127 deaths resulted from these principal zymotic diseases, against 107 and 102 in the two preceding weeks. These 127 deaths were equal to an annual rate of 4·3 per 1000, which was 2·6 per 1000 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 39 in each of the two preceding weeks, rose to 52 last week, and included 35 in Edinburgh and 12 in Glasgow. The deaths from whooping-cough, which had increased from 38 to 41 in the three preceding weeks, further rose to 45 last week, of which 24 occurred in Glasgow and 17 in Edinburgh. The 6 fatal cases of diphtheria exceeded by 4 the number in the preceding week, and included 3 in Glasgow. The 6 deaths referred to different forms of "fever" were all recorded in Glasgow, and of the 3 fatal cases of scarlet fever 2 occurred in Edinburgh. The deaths from diseases of the respiratory organs in these towns, which had been 154 and 165 in the two preceding weeks, declined again last week to 128, but slightly exceeded the number in the corresponding period of last year. The causes of 53, or more than 8 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28·2 and 34·6 per 1000 in the two preceding weeks, declined again to 29·5 during the week ending May 1st. During the past four weeks of the current quarter the death-rate in the city has averaged 32·1 per 1000, the rate during the same period being 17·1 in London and 28·0 in Edinburgh. The 198 deaths registered in Dublin during the week under notice showed a decline of 34 from the number in the preceding week, and included 36 which were referred to the principal zymotic diseases, against 36 and 41 in the two preceding weeks; of these, 16 resulted from measles, 13 from whooping-cough, 3 from "fever," 2 from diphtheria, 2 from diarrhœa, and not one either from small-pox or scarlet fever. These 36 deaths were equal to an annual rate of 5·4 per 1000, the zymotic death-rate during the same period being 1·5 in London and 10·5 in Edinburgh. The fatal cases of measles, which had been 15 and 19 in the two preceding weeks, declined again to 16 last week. The deaths referred to whooping-cough, which had been 14 in each of the two preceding weeks, were 13 last week. The mortality from diphtheria and from "fever" slightly exceeded that recorded in the preceding week. The 198 deaths in Dublin last week included 33 of infants under one year of age and 34 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a marked decline from the numbers recorded in the preceding week. Nine inquest cases and 9 deaths from violence were registered; and 77, or more than a third, of the deaths occurred in public institutions. The

Hosted by Google

causes of 15, or nearly 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR F. A. HARRIS and Surgeon-Captain C. W. Reilly have joined at Woolwich.

The under-mentioned Surgeon-Lieutenant-Colonels to be Brigade-Surgeon-Lieutenant-Colonels:—Oswald G. Wood, vice E. J. Fairland, retired; John Martin, vice T. J. P. Holmes, retired. The under-mentioned Surgeon-Captains to be Surgeon-Majors:—William E. Berryman and Sidney E. Duncan. Surgeon-Captain Harry E. B. Porter resigns his commission.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Major R. Ross (Madras) has made over, and Brigade-Surgeon-Lieutenant-Colonel A. F. Dobson (Madras) received charge of, the office of the Residency Surgeon at Bangalore. The services of the under-mentioned officers are placed temporarily at the disposal of the Government of Madras for employment on plague duty:—Surgeon-Lieutenant Illington, Surgeon-Lieutenant Browne, and Surgeon-Major Waddell. The services of the under-mentioned officers are placed temporarily at the disposal of the Government of Bombay for employment on plague duty:—Surgeon-Lieutenant-Colonel Hamilton, Surgeon-Major Routh, A.M.S., Surgeon-Major Deane, A.M.S., Surgeon-Captain Jones, A.M.S., Surgeon-Lieutenant Fleury, A.M.S., Surgeon-Lieutenant King, Surgeon-Captain Jackson, A.M.S., Surgeon-Lieutenant James, and Surgeon-Lieutenant Dee.

NAVAL MEDICAL SERVICE.

Deputy-Inspector-General of Hospitals and Fleets Henry Macdonnell has been promoted to the rank of Inspector-General of Hospitals and Fleets, and Fleet-Surgeon Robert Grant has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets. Fleet-Surgeon Kelly Conway has been placed on the Retired List, with permission to assume the rank of Deputy-Inspector-General of Hospitals and Fleets.

The following appointments are announced:—Staff-Surgeons: Samuel W. Vasey to the *Barfleur*, and James C. F. Whicher to the *Caledonia*. Surgeon: Edward Cooper to the *Victor*, additional.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain S. H. Moore to be Surgeon-Major.

VOLUNTEER CORPS.

Artillery: 1st Essex (Eastern Division, Royal Artillery): Francis Augustus Brooks, M.D., to be Surgeon-Lieutenant. *Rifle:* 3rd Volunteer Battalion the South Wales Borderers: Surgeon-Captain J. W. Davies resigns his commission. 1st Volunteer Battalion the Royal Sussex Regiment: Charles Burnett Scott, M.D., to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Royal Sussex Regiment: Surgeon-Lieutenant G. L. L. Hawken resigns his commission; George Black, M.B., to be Surgeon-Lieutenant.

THE HEALTH OF EUROPEAN TROOPS IN INDIA.

Lord George Hamilton's despatch may be fairly regarded as proposing very moderate remedial measures for the consideration of the Government of India. The Anglo-Indian papers appear to consider that these do not go far enough to meet the requirements of the case; whereas, on the other hand, Mr. Walter S. B. M'Laren, the chairman of the British Committee of the Federation for the Abolition of the State Regulation of Vice, urges the Secretary of State for India to withdraw his despatch and substitute for it another of which his committee can approve. We may, therefore, infer that the Secretary of State has been studiously moderate in the expression of his views on this difficult subject. The committee make a great point of the examination of women, to which they are strongly opposed. It is, no doubt, impossible to tell whether a woman is diseased or not without examination, and we fail to see the force of the objection to it in the case of a woman pursuing the occupation in question, where reasonable grounds exist for the belief that she is diseased and the examination is conducted by one of her own sex. As regards what is urged about the discouragement of vice and placing the soldier in an environment tending to develop his best physical, moral, intellectual, and religious faculties, we can only say that high-sounding generalisations of this kind are of too vague and visionary a character to form a basis of practical action. The aim of the authorities in India has practically been in this direction, and there is no reason whatever against efforts being made to remove temptations and discourage vice; but even a small amount of observation and experience of life and of human nature suffice to show how little reliance can be placed on them as safeguards against sexual temptations. The reasons for regarding constitutional syphilis as a contagious and hereditary malady do not admit of controversy, and we cannot see why it should not be placed on the same footing as other contagious diseases which endanger the health of the community, or why those measures which have been found necessary and efficacious in the one case should not be applied in the other. By all means let efforts at moral suasion be carried out; but sensible people will not be disposed to neglect physical methods of a direct and practical nature for limiting the spread of such a dangerous and preventable disease as syphilis.

NON-DIPHTHERITIC SORE-THROAT AMONG SOLDIERS.

The place of honour in Professor Simon Duplay's *Archives Générales de Médecine* for April is accorded to a report on Non-diphtheritic Membranous Sore-throat, by Surgeon-Major P. A. Cassedebat of the 2nd Zouave Regiment. During about twenty months, from January, 1893, to September, 1894, no fewer than 134 cases of this affection occurred among the men of his corps, of which the strength was between 750 and 800. The writer sets forth the details of each case in tabular form, including an epitome of the bacteriological examination, and supplements this information by descriptive letterpress, which is divided into ten sections. A plan of the barracks, showing the general arrangement as well as the position of the infected beds, is also appended. In all the cases the false membrane was firmly adherent to the subjacent tissue, and when removed did not dissolve readily in water. Slight cases of sore-throat, with fugitive, easily displaced membranes, were excluded from the collection, as were also all sore-throats that were dependent on measles, scarlet fever, syphilis, follicular tonsillitis, or ablation of the tonsils. At the onset the only way to establish the diagnosis from diphtheria was by the aid of the microscope, but the true character of the complaint soon declared itself, the vast majority of the patients being fit for duty in four or five days. The bacteriological examination revealed an immense assemblage of microbes of various kinds, but the streptococcus alone was constantly present. It is to this micro-organism that Surgeon-Major Cassedebat attributes the origin of the disorder; and he likewise is of opinion that the varying physical character of the false membranes may be due to a plurality of streptococci. A considerable portion of the paper is devoted to an inquiry into the contagiousness of the affection, but apparently its incidence among soldiers is but little influenced by propinquity of habitation.

DEATHS IN THE SERVICES.

Surgeon-General James Tyrell Carter Ross, C.I.E., F.R.C.S., Bengal Army (retired), aged seventy-four. He served in the Sutlej and Punjaub campaigns and in several Indian expeditions between 1851 and 1854, in the Indian Mutiny campaign, in expeditions from Allahabad and at Khoongunge, and Futtehghur; was principal medical officer in the Duffla expedition of 1874, and took part in the Zulu campaign of 1879.

Deputy-Surgeon-General Charles T. Eves, Indian Medical Service (retired), at Brook's Lodge, Cheltenham, on April 26th last, aged sixty-eight years.

INSPECTION OF MEDICAL EQUIPMENT AT LAHORE FORT.

The Principal Medical Officer of Her Majesty's forces in India, accompanied by several officers, recently made an inspection at Lahore of some new equipment designed for field service, which consisted of the "Tortoise" pattern tent adapted to Indian requirements, a new pattern stretcher for mule transport, and a portable field stove.

WE have received from Messrs. Novello, Ewer, and Co. a "Hymn in Commemoration of Queen Victoria's Nurses" ("How Shall we Teach our Children?"). The words are written by the Dean of Rochester and the music is composed by Dr. G. C. Martin.

PUBLIC HEALTH (SCOTLAND) BILL.

To the Editors of THE LANCET.

SIRS,—A new Scottish Public Health Bill is before Parliament at this time, and will soon pass, more or less modified, into law. Surely it is becoming that a measure so important to the lieges, and withal affecting our own profession very closely, should be seriously considered by medical practitioners all over Scotland as long as its terms are open to amendment, and yet there is little displayed interest in the subject. It is thirty years or more since the last general Act was passed, and it may be that a third of a century will again elapse before the present Act—when we get it—is again considered.

The Bill slurs over the altogether wrong interdependence of the sanitary officials. It ought to distinctly enjoin the due subordination of *all* the staff to the medical officer of health. Every good organisation, it is surely needless to assert, must have a single controlling head or centre. But this new Bill leaves the relative position of head medical officer and head sanitary inspector as it exists—i.e., at once coördinate and undefined. While medical officers of health, for the sake of harmony, and with a due regard to their position as highly trained and thoroughly educated gentlemen, demand their proper place—viz., that of the recognised heads of the sanitary administration in their particular jurisdictions—on the other hand, it can be easily shown that this is the right and due course to be followed not only in the interests of the public but also in those of the profession at large. The family medical attendant has a somewhat difficult part to play when his patients are the subjects of infectious disease as well in connexion with notification as in regard to the house, its drainage and water-supply, isolation, removal to hospital, and it may be the treatment also of his patients. Even his diagnosis is occasionally called in question. Surely in all such delicate questions it is right that he should be in relation with an authoritative medical brother professional, and not be liable to be hauled over the coals by, it may be, an ignorant and presumptuous sanitary inspector. We do not believe much good will result except from close and confidential working between the practitioner and the chief medical officer of health. And this brings us to consider the propriety of modifying the Notification of Diseases Act. Dr. Cameron, the energetic medical officer of health to Banff, Moray, and Nairn, suggested some time ago that a *single* notification of infection should be enough from each house on the occasion of an outbreak, while the medical attendant should be paid for granting a certificate giving a clear bill of health after termination of the illness for school and other purposes. With this change on the one hand, on the other we might hope to have legal notification of *every* infectious disease, including measles, whooping-cough, mumps, and, let us hope, by-and-by, tuberculosis and syphilis. In addition, we ought to be paid for such certificates. What other profession would have allowed itself to work so long for nothing? It is high time that we should bestir ourselves in this and other directions and refuse to be the slaves of an ungrateful public. There are many other questions which both the profession and people at large ought to study before this Bill becomes law, such as clauses against dangerous trades, overcrowding, &c. But it would take a long time to discuss such matters with advantage. Education of the mind excites general attention, but the care of our bodies little or none. We must e'en bear with it so. I am, Sirs, your obedient servant,

Dingwall, May 1st, 1897. WILLIAM BRUCE.

"NOTES ON ONE YEAR'S SURGICAL WORK."

To the Editors of THE LANCET.

SIRS,—I am much obliged to Mr. T. S. Ellis for his criticism in THE LANCET of May 1st of my remarks on the treatment of flat foot. The reason which led me to adopt the method I described was what happened in a case of hallux rigidus accompanied by flat foot in which I treated the joint by excision and found that the flat foot was at the same time relieved. On trying the treatment in uncomplicated flat foot I found it efficacious. And, after all, it is practical results and not theoretical considerations which is the highest criterion of the utility of any procedure.

I am, Sirs, yours faithfully,

Beaumont-street, Oxford, May 5th, 1897. H. P. SYMONDS.

"THE DECLINE OF THE SCOTTISH UNIVERSITIES."

To the Editors of THE LANCET.

SIRS,—In an annotation in THE LANCET of May 1st you deal with what you call the "Decline of the Scottish Universities." As the annotation is presumably of editorial authority, I trust you will allow me to make a few remarks on the subject, which is of great importance to the large number of Scottish graduates who read THE LANCET. The "decline" is in the number of students at present attending our universities, and you give your view of the causes of the diminution in the matriculation rolls; and the position advanced by you is, in general, that relatively to universities elsewhere examining and teaching are in our colleges conducted on a low standard, and that therefore students who otherwise would have come to Scottish universities go elsewhere to share in the "generous rivalry for qualifications and honours worth the contest." You state that "in the Arts Faculty the standard of proficiency on admission to the curriculum has been too low." If you refer in this charge to the state of matters some years ago it is certainly true; it is quite as certainly untrue now. The entrance examination in Arts is at least as severe, and is as stringently enforced, as in any university in the empire. The questions are set and the examination is supervised by a joint board of examiners elected from all parts of Great Britain by the courts of the four universities so as to ensure that the standard will be maintained and undue favour shown to no candidate. Of this anyone will be satisfied who will look at the questions set and at the *personnel* of the board. You speak disparagingly of the instruction given in the classes—that it "has savoured more of the upper form in schools than of a university." It is true that instruction which might be so characterised has been given, and is being given, and will continue for a short time still to be given; but degree students do not attend such classes, which are not recognised for graduation at all. These lower classes exist to meet what has hitherto been a special Scottish requirement.

To the Universities of Oxford and Cambridge which you contrast with ours students go who are almost entirely from the upper and rich middle classes of society and who have previously been educated at expensive secondary schools. To the Scottish universities students are drawn from every social stratum, and secondary schools until recently have been few and have existed only in four or five of the larger towns. The ordinary school, therefore, had to be in touch with the university, and the gap of the missing secondary school was bridged by the old parochial master doing higher work than his English *confrère* and by the university having special classes which went half-way to meet him. But in Scotland secondary education is making rapid progress, how rapid may be judged by the large numbers of Junior and Senior Leaving Certificates that are annually earned at examinations conducted by the Scottish Education Department at Dover House. So rapidly is higher education spreading in Scotland that the Junior University Classes will soon cease to exist, and an Ordinance has already become law by which the universities can at an early date close these classes entirely. But, as I have already said, these are not degree classes at all. The degree classes are altogether apart; and seeing that they have been and are being conducted by such men as Lord Kelvin, Jebb, Ramsay, Murray, the present Master of Balliol, Butcher and Saintsbury, it is not at all likely that the instruction is less comprehensive or elaborate than that given by college tutors at Oxford or Cambridge. The Scottish University classes are now smaller, not because of inferiority in examination or teaching, but because of the great improvement and spread of secondary education in the country. This allows of men who are going into commercial life and who do not desire a degree, but who do want a sound education up to a certain level, finding what they require amply provided in the public schools, thus leaving the universities free to devote themselves entirely to the higher learning. The very circumstances you have urged in explanation of the decline in numbers did to some extent actually exist in former years, when the classes were

Hosted by Google

crowded, and it is because of the very measures you indicate as improvements having been given effect to that for a time the attendance has declined. But it is a decline in numbers only, not a decadence of power or aim. On the contrary, just as in all organic transition there is a temporary disturbance of function, so the fall in numbers in our universities marks the transition to a new and higher academic life in Scotland.

Dealing more particularly with medical education you censure the lecture system in Scotland as wasting the time of the student. Much can be said on both sides of this question. It depends greatly on the subject, and especially on the teacher, as to whether five lectures in the week or three will be better for the student, and this the Scottish teacher has now by Ordinance in his own hand. A course consists, not of a hundred lectures, but of a hundred meetings of the class. The professor may lecture or demonstrate practically or teach tutorially or engage the student in manipulation work according as he, with the sanction of the Senate, may determine. Your objection of over-lecturing, therefore, can no longer be urged against the Scottish universities. But if the Scottish medical professors have in the past given more lectures than their English brethren, they have not on that account done less in the way of clinical teaching than has been the case south of the Tweed; on the contrary, they have done much more. The Scottish hospital physicians and surgeons attend in the wards every day, and every day they give clinical instruction. The Scottish student and the Scottish teacher of medicine alike work with a constancy that does not prevail in England in matters both theoretical and practical. It may be said that this will paralyse original research on the part of the professor, but we can point to the two greatest achievements of the century—that of anæsthesia by Simpson, a hard-working professor in Edinburgh, and antiseptic surgery by Lister, when he was lecturing five days a week in the University of Glasgow and teaching clinically five days a week in the Royal Infirmary.

The final reason you give for our decline is certainly a singular one, coming as it does after the others. Having shown to your own satisfaction that the Scottish system of teaching is so bad that it is ruining us, you say a further cause of our decline is the reinforcement of the schools in England and Ireland by teachers and examiners from the schools of Scotland. Your countrymen believe that it requires a surgical operation to get a joke into a Scotsman's head. Surely the writer of your annotation must be a brilliant surgeon. It is true that many Scottish graduates go to England and Ireland, and Canada and Australia, and India and Africa; but while we lose their services at home they spread the reputation of their universities over the globe and send us students from every part of it. While we give, we also take. Of ours, you have in London Ferrier, and Lauder Brunton, and Duckworth, and Ramsay the chemist, and at Oxford the Master of Balliol; of yours, we have in Edinburgh Turner and Greenfield, and Butcher and Saintsbury; in Glasgow we have Lord Kelvin; from Ireland Bower and Lodge; and, lately, Jebb from England and Jones from Wales. We give of our best where we can spare, and we take of yours as freely as we bestow. A reciprocity of this kind is no sign of decadence. If your annotation was written in any gloomy anticipation that the source from which many of the best medical teachers in England have been drawn is in any danger of drying up, let me assure you that your fear is groundless. In the future, as in the past, the Scottish universities will do their duty alike to Scotland and to you. I am, Sirs, yours faithfully,

Glasgow, May 4th, 1897. D. C. MCVAIL.

To the Editors of THE LANCET.

SIRS,—In an annotation in your issue of May 1st on the "Decline of the Scottish Universities" prominence is given to some remarkable statements which will rather startle Scottish graduates. The standard of the arts entrance examination may be low in Scotland, but it is notoriously so at Oxford and Cambridge; and the reason that Scottish graduates in arts often afterwards take an arts course at Oxford or Cambridge is not that the education there is of higher quality, but that the prizes are greater. It is the value of the exhibitions, scholarships, and Fellowships that is the attraction, for the Scottish degree with honours is quite as good and as much prized as the English.

The writer says the Scottish M.A. "has never carried with it the same guarantee of thoroughness and academic status implied by that of Cambridge or Oxford." It is a matter of common knowledge that the pass standard at both English universities is disgracefully low, and that often a candidate who has one good subject gets through although his others are weak; whereas in Scotland the standard is much more even, and the knowledge therefore more uniform and thorough. If one system savours more of the upper school form, surely it is the English with its system of tutors and residential colleges. The decline in the number of matriculations at the Scottish universities is almost entirely confined to the medical faculty—e.g., at Edinburgh in 1891-2 there were 1951 medical students, whereas in 1895-6 the number had fallen to 1455. No doubt some of the reasons given by the writer of the annotation may have contributed to this result in a minor degree, but it is much more probably due to the institution of the five years' curriculum, which came into force in 1892, and to the present overcrowded condition of the medical profession—two considerations which he neglects altogether.—I am, Sirs, yours truly,

W. CUNNINGHAM MILROY, M.A., M.D.Edin.

Wigan, May 3rd, 1897.

"RIGHT-HANDEDNESS."

To the Editors of THE LANCET.

SIRS,—The following case, which I met with some twenty years ago, may perhaps be of interest in connexion with the hereditary transmission of acquired peculiarities—a question which has recently been discussed in your columns. The report of the case as published in the Transactions of the Northumberland and Durham Medical Society, Session 1877-78, page 68, is as follows:—

Dr. Byrom Bramwell showed a case of Congenital Under-development of the Left Eyeball or "Microphthalmos," and said: "The condition which this patient presents is a rare one. Dr. Argyll Robertson, of Edinburgh, whose experience is, of course, very great, tells me he has met with few cases, and that little is to be found on the subject in English literature. The patient is aged nineteen. The smallness of the left eyeball was first noticed six weeks after birth. The external parts of the eye are well formed; vision is almost *nil*, owing to the alterations in the optic disc and surrounding portion of retina. There is an interesting point in connexion with the case. The mother, about a year before the birth of this child, received a severe blow on the right eyeball. The globe was destroyed. She was laid up for three months. This child was born about a year (her memory is not accurate on this point, it may be a little more or a little less) after the receipt of the injury. The connexion is an interesting one, and it may be that the injury to the mother's *right* eye had something to do with the under-development of the child's *left* eye. The children born before and after this one are naturally formed."

I am, Sirs, yours faithfully,

Edinburgh, May 3rd, 1897. BYROM BRAMWELL.

A PECULIAR AFFECTION OF THE KNEE-JOINT.

To the Editors of THE LANCET.

SIRS,—The two following cases of disease of the knee-joint which I have met with may be of interest to the profession, as they answer to nothing that I can find in the leading English and German text-books on surgery. The principal features of both consist of acute swelling of one knee-joint occurring suddenly and without obvious cause in delicate young men further characterised by absence of inflammatory symptoms, accompanied by little or no pain, and followed by complete recovery.

CASE 1.—The patient was a thin, weak-looking man, aged twenty-five years. One afternoon after a tennis party, at which, though he played one game, nothing unusual occurred, he found his left knee felt stiff and was swollen. On my examining it the next morning it was found to be moderately swollen, fluctuating, but not tender, the skin was not œdematous or red, and did not feel warm. The patient felt no pain beyond a feeling of stiffness if he tried to bend it. He was told to keep the leg in a horizontal position, and fly blisters were applied. After four days, there being no improvement, a plaster bandage was applied and worn for three weeks, then with a knee-cap and the use of a walking-stick he soon recovered.

CASE 2.—A mealy-faced young man, aged eighteen years, after wheeling about a light barrow one morning felt his right knee become rather painful. He walked home and found that it had swollen. When seen the next day the joint was found to be moderately swollen and gave fluctuation;

Hosted by Google

there was no tenderness, redness, or œdema of the skin, but he felt a little pain when he walked. The knee was painted with strong iodine liniment for a few days; no improvement followed. A plaster bandage worn for a few weeks caused the fluid to disappear, and with a leather splint he was soon able to work again in the fields, and quite recovered the use of his knee.

Neither of these patients was a "bleeder." Amongst several medical men with whom I have discussed these cases I may mention that Dr. Genth of Schwalbach tells me that he has met with cases apparently similar; he states that his occurred in nervous young men, and that he found, like myself, that blisters were useless, though the local treatment by baths was very beneficial. As regards pathology, synovitis of the knee-joint, requiring either severe injury or septic infection, seems to be excluded, also rheumatism from the monarthritic nature of these cases and struma from their general nature. The only feasible explanation seems to me to be that they are due to a tropho-neurotic change in the synovial membrane occurring in a debilitated subject from some obscure cause.—I am, Sirs, yours truly,

WALTER G. EARLE, M.R.C.S. Eng., L.R.C.P. Lond.

Tunbridge Wells.

*** We agree with our correspondent in thinking these two cases of interest, but we are inclined to look upon them as examples of a synovitis resulting from very slight traumatism in an unhealthy subject. In each case there was a great likelihood of a slight injury having occurred, and certainly such cases are by no means rare after tennis. The speedy cure which resulted from the use of splints is in favour of this diagnosis.—ED. L.

"ACUTE PEMPHIGUS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 13th, which I received to-day, I read a Clinical Note by Dr. Jón Jónsson on "Acute Pemphigus." It might be of interest to your readers to know that I have seen two cases of "acute *generalised* pemphigus," one in a young man, aged twenty-two years, in the year 1894, and the other in a boy aged thirteen years, in October last. The young man died on the fifth day. The boy lived, and was at the moment supposed to be out of danger, up to the eighteenth day, when he died very suddenly. The symptoms in both cases were exactly those described by Dr. Jónsson and Dr. Priestley. There were vesicles on the inside of the mouth (buccal mucous membrane), but no eczema. I am, Sirs, yours truly,

F. G. CORBIN, M.D. McGill.

Chascomús, Argentine Republic, April 4th, 1897.

FRACTURES OF LONG BONES IN SCURVY-RICKETS.

To the Editors of THE LANCET.

SIRS,—At the meeting of the Medical Society of London held on April 11th I showed an infant suffering from multiple spontaneous (so-called) fractures of long bones, dependent, in my opinion, on scurvy-rickets. In your report of the proceedings[1] you mention that Mr. Morgan thought my diagnosis questionable on the ground that hæmorrhages and fractures in scurvy rickets were usually near the epiphyses and not, as in my case, in the centres of the shafts. As the President did not allow me to reply to Mr. Morgan's criticism at the time, may I venture to do so in your columns?

Central fractures of long bones may occur in addition to separation of epiphyses and hæmorrhages beneath the periosteum in the course of scurvy-rickets. I have Dr. G. A. Sutherland's permission to refer to one of his cases of scurvy, as yet unpublished, in which such conditions were diagnosed during life by him, and verified by myself post mortem. I did not see my own patient until several months had elapsed since the fractures had been produced, and at this time there were certainly no sub-periosteal effusions. Yet, from the history of swelling and bruising of the limbs, I have little doubt that hæmorrhages were present at first. Such hæmorrhages are very quickly absorbed. The point which needs further investigation is whether these central fractures are the cause or the consequence of the extravasations. Effusions beneath the periosteum may lead to fragility of the bones by depriving them of their normal nutrition and support. On the other hand, the general tendency to hæmorrhage in scurvy may cause sub-periosteal extravasation at the time the fractures occur. Opinions on this point were not forthcoming when the case was shown. The time for discussion was limited, it is true; but if in a society like the Medical Society of London discussion of cases is invited at all, I think that answers to criticisms should be allowed. Otherwise the genuineness of cases exhibited must remain for ever doubtful and the value of facts observed may be impaired.

I am, Sirs, yours truly,

May 3rd, 1897. LEONARD G. GUTHRIE.

[1] THE LANCET, April 17th, 1897.

"THE HOSPITAL REFORM ASSOCIATION: REPORT OF THE COMMITTEE APPOINTED TO INQUIRE INTO THE WORKING OF THE SPECIAL HOSPITALS OF LONDON."

To the Editors of THE LANCET.

SIRS,—THE LANCET of April 17th contains a letter signed by the secretary of the Central London Throat and Ear Hospital upon the shortness of our visit to his institution and stating that important matter supplied by him had been omitted in our report. In reporting upon forty-one institutions it was impossible to spend hours over each visit, as he suggests we should have done. In his case we called three times before finding him at home. In regard to the second point, if we had sent to press one-half of what the various secretaries would have liked said about their particular institutions no journal would have published the report on account of its length. Since publishing the report we have been informed by the secretary of the British Mental Hospital that the annual subscription to that hospital in 1895 was £292. We were unable to publish these figures at the time, as this institution has issued no report since 1894.

We are, Sirs, yours faithfully,

W. KNOWSLEY SIBLEY, M.D. Cantab.,

May 4th, 1897. ERNEST SNAPE, M.D. Brux.

"THE QUESTION OF THE SECOND OVARY IN OVARIOTOMY."

To the Editors of THE LANCET.

SIRS,—The question raised by Mr. Clement Lucas as to the necessity for the removal of the second ovary in ovariotomy is a very important one. As one who has not operated extensively, but who, nevertheless, has seen a considerable amount of gynæcological work, I should feel obliged by your allowing me space to record my views, whatever value they may have. I have in the past, acting on the ordinarily accepted views of eminent gynæcologists, removed ovaries that in the light of my own experience since I would not think of removing now. I have in some cases removed both ovaries, while in others I have removed only one, being influenced, as Mr. Clement Lucas evidently is, by the particular circumstances of each case. I firmly believe there can be no fixed, defined, and inalienable rule in these cases. I remember years ago removing a cystic ovary from a young woman, unmarried, leaving the other, which was enlarged and tender. She made an excellent recovery, but when well enough to be discharged and get about she began to complain of symptoms pointing to the ovary which was left behind, and she was repeatedly sent to me to know if she had not another tumour coming and if it was not advisable to have another operation. I saw no reason for it and refused, and this young woman is now perfectly well. There were pain and tenderness, but I did not consider these sufficient to justify another operation. One cannot avoid the feeling that in this case the second ovary might have been removed had I been strongly impressed with the need for it at the time of operation. We might have had this case to swell the number of double removals, and the tender condition and enlargement would have been employed as arguments in justification.

I know of a case of cyst of the broad ligament which I was about to remove five years ago, but which, owing to the very alarming symptoms occasioned by the anæsthetic, I was obliged to desist from doing when just about to enucleate it. The operation was immediately stopped and the abdomen

Hosted by Google

closed. From that day to this the cyst has not enlarged; indeed, it underwent some degree of diminution. I have seen the patient at intervals of a few months since and she has continued very comfortable and able to attend to her business. During the time I had the patient under observation previously to the operation the cyst had been increasing, and I only decided to operate because of the disturbance and pain it was causing in its neighbourhood, as well as rendering the woman unfit for her duties and giving her great general discomfort. Its presence does not now cause these symptoms in anything like the same degree, and, as I have already said, she attends to her daily duties, which are of an arduous kind. Why the cyst ceased to increase is another question, but it may have been *in some measure* due to the fact that I made her rest absolutely for six months.

I accidentally discovered a cyst of the ovary when attending a woman four years ago for another matter. It had not increased when I last attended her a few months ago, and she at present suffers only a little from it. She does not know of its existence. Why should she so long as it gives such slight trouble and she is quite able for her duties? She has had two children since I discovered the cyst, and if it has remained *in statu quo* for four years (and perhaps for four years previously to that) may it not remain so for four, or even fourteen, more? I may also instance the case of a young married woman in whom a tumour (cystic) of one ovary has existed to my knowledge for years. It has at times caused a good deal of suffering, and on one occasion I almost decided to remove it. Several months of absolute rest, however, with some treatment, helped her greatly, and she has been able to attend to her household affairs with a considerably greafer degree of comfort than previously. I have known of the existence of this cyst for six or seven years, and it does not increase.

These, possibly it may be advanced, are not instances quite analogous, except the first, to those mentioned by Mr. Clement Lucas, inasmuch as in his the abdomen was opened, and the advocates for removal would say that it would be better to remove the organ then than for the woman to undergo the trouble, anxiety, and suffering of a second operation, with its consequent risk and expense. The risk, of course, is small now, thanks to the progress made in surgery during the last quarter of a century. But there is risk, and it ought to be avoided, to say nothing of the other concomitants of an operation. But if there is a reasonable hope that the ovary may not get worse or may recover, I think the woman, especially if a young one, ought to have a chance and the ovary should be left, and I think it may be fairly said that the cases cited show that ovaries to some extent diseased may be left sometimes with a very fair prospect that they may not only not cause increased trouble in the future, but that they may remain stationary or even recover. If, then, some diseased conditions of the ovaries remain quiescent for years, improve, and even get well, we ought not too hastily to conclude that operative interference is necessary, but should keep our patients under observation and treatment. I am confident that some operations may be avoided by this plan, and the subjects of the disease be enabled to pursue their daily duties with comfort. If the time comes for operation the case can be dealt with then just as well as earlier, provided one does not allow it to go too far until dangerous complications arise. I am quite alive to the necessity for early operation. I am sure, however, we will lose nothing by waiting and watching, selecting the proper cases for such a course.

I am, Sirs, yours truly,

D. THOMSON, M.D. Glasg.

Lowndes-street, S.W., May 4th, 1897.

TUBERCULOSIS IN DAIRY CATTLE.

To the Editors of THE LANCET.

SIRS,—In the issue of THE LANCET of May 1st your Irish correspondent refers to the resolution passed by the Dublin University Biological Association concerning the prevalence of tuberculosis among dairy cattle. He further states that it is reassuring to find in the report of the Cowkeepers' Association that the result of a veterinary examination by two gentlemen shows only 4 cows out of 1500 examined were affected with tuberculosis. There are some considerations which would lead one to place very small reliance on the results obtained by these gentlemen, to which I wish to draw public attention. From a return furnished to me by the Veterinary Department of the Privy Council Office, Ireland, I take the following statement: "It appears from the departmental records that the post-mortem examination of the lungs of cattle slaughtered by direction of the Veterinary Department between the years 1888–1893 in the North and South Dublin Unions as having been in contact with cattle affected with pleuro-pneumonia, or otherwise exposed to the infection of that disease, showed that the proportion of cases in which the *lungs* were affected with tuberculosis was almost 5 per cent. The majority of cattle slaughtered were dairy cows." It is evident from this statement that if only four out of 1500 cows are now affected with tuberculosis there must be a most marked improvement in the health of cattle in this district. Indeed, such a marked change in so short a time is sufficiently remarkable to call for some explanation. So far from any explanation of this improvement being forthcoming it is a matter of common knowledge that little or nothing is being, or has been, done to improve the state of the dairy yards, the unsanitary condition of which has been so often pointed out. Taking these facts into consideration, and remembering that the extraordinary prevalence of tuberculosis among dairy cattle in general has been amply proved by numerous statistics, we shall, I think, be justified in doubting these results so long as the methods by which they were obtained are open to suspicion. Professor McFadyean, when summing up the results of his experiments for the recent Royal Commission, states: "The conclusion that appears warranted is that ordinary clinical examination is almost valueless for the detection of tuberculosis in its early stages." Over and over again in his published works this great authority on veterinary pathology has stated that ordinary clinical examination even in the hands of the most skilled and experienced veterinary surgeons is incapable of pointing out all the animals affected with tuberculosis. Unless some more accurate means of diagnosis is used than ordinary clinical examination affords veterinary surgeons merely leave themselves open to the charge of incompetence by certifying animals to be free from tuberculosis. It would appear that Koch's tuberculin in the hands of skilled surgeons is the most accurate method of diagnosing tuberculosis of cattle, and where it cannot be used most veterinary surgeons decline to express a decided opinion. We cannot, then, accept any statement as to the number of tuberculous cattle in our dairy yards which is not based on examination with tuberculin or the results of post-mortem examination. Was this test employed by the inspectors who reported to the Cowkeepers' Association? If so, where are the tabulated returns of the cattle examined? The answer is, I think, that these returns do not exist, because the method was not used, and in consequence the report is valueless.

I am, Sirs, yours faithfully,

T. PERCY C. KIRKPATRICK, M.D. Dub.

Dublin, May 4th, 1897.

"THE SWEDISH SYSTEM OF PHYSICAL EDUCATION."

To the Editors of THE LANCET.

SIRS,—If you would kindly allow me space in your next issue I should be glad to efface an impression which I regret to have made. In your review of my booklet on the above subject exception is taken to one observation. Your reviewer writes: "The English medical profession is charged with 'insular prejudice against anything branded as foreign.'"[1] Reference was here intended to the British nation as a whole. As a general and national characteristic it would be difficult to deny that John Bull entertains a certain scorn for the foreigner and for what is foreign, and has an ingrained belief in the superiority of himself and his opinions. This remark, however, was not specially directed against the medical profession; for does she not gracefully acknowledge that many of the brightest jewels in her crown have been set there by other than English hands? In proceeding I have ventured to state that that learned body is characterised by a conservative spirit, but between "conservative spirit" and "insular prejudice" exists a distinction which certainly constitutes a difference.

Believe me, Sirs, yours very truly,

Bristol, May 4th, 1897. THEODORA JOHNSON.

A QUESTION OF COURTESY.

To the Editors of THE LANCET.

SIRS,—May I ask for your opinion on the following case? I have for some twenty years held one of the parish appointments of this district, so am well known over it by the gentry and others, and the extent of the boundaries of the district are well defined. In December, 1896, I was attending a woman, a parish patient, in an outlying cottage (a miserable building). She was evidently suffering from some uterine trouble, but being surrounded by three or four very young children she could get no proper attention there. After a good deal of difficulty I persuaded her to come into the Cottage Hospital here, to ascertain what was wrong and treat her accordingly. A lady guardian living near and a parson's sister in January got interested in her case, and, without ever communicating with me, took over Miss Annie M'Call, M.D. Bern, &c., of 131, Clapham-road, S.W., and also a district nurse. The former examined my patient straight away, and the latter persuaded her not to come into the Cottage Hospital, but to go to Euston-road hospital, where, as far as I can ascertain, the right ovary was removed and the uterus, which was retroflexed, was replaced. They sent her out again under a month from the operation to a poor cottage without ever communicating with me even then in the interests of the patient, and she came back on to my hands in a very weakly and hysterical state, and is at present in the Cottage Hospital, where I trust she may get stronger. I wish specially for you to express an opinion whether a woman who happens to have taken a doctor's diploma is exempt—and we poor men not so—from the unwritten law of courtesy in this noble profession.

I am, Sirs, yours truly,

FREDERIC DANIELL MILLER, M.D. Durh., &c.

Horwoods, Basingstoke, April 30th, 1897.

*** Our correspondent has much reason to complain of want of courtesy on the part of the ladies concerned in this case, who, at the least, should have communicated with and consulted him. Surely ladies who are members of our profession, so far from being exempted from its rules, should be particularly scrupulous in their observance.—ED. L.

MEDICAL MEN AND SUBPŒNA.

To the Editors of THE LANCET.

SIRS,—Thinking that my experience may be of use to other medical men and save them having to waste four or five days at the law-courts for nothing I ask if you will be kind enough to give me a little of your valuable space for my letter. Some time ago I received a subpœna commanding me to appear before the Court of Queen's Bench to give evidence concerning an accident case I had attended, and with the subpœna I received half a crown. I protested; but on looking the subject up I came to the conclusion that I was bound to answer to my subpœna, but need not give evidence. The case came on before the Lord Chief Justice. When I was called into the box I refused to be sworn and asked his lordship how I ought to act. He very kindly told me that not only was I perfectly justified in refusing to give evidence, but that I might have ignored the subpœna and the court would have taken no notice of my contempt.

Half-a-crown is not a reasonable *viaticum* to offer a medical man, and a subpœna served upon him with that amount can be ignored.

I am, Sirs, yours faithfully,

WILLIAM F. CLARKE, M.D. Lond.

West Kensington, May 5th, 1897.

UNIVERSITY OF CAMBRIDGE.—The decision of the Senate on the proposal to admit women to titular degrees will be taken on May 21st in the Senate House. The voting on the primary resolution will take place between 1 and 3 P.M. Energetic canvassing for and against the resolution is being pursued by committees of graduates in Cambridge and London. Dr. Nansen has made to the University a gift of £50 for the benefit of the department of geography. The University of Madras, like those of Calcutta, Bombay, and Allahabad, is to be affiliated to Cambridge. At the Congregation on April 29th Mr. R. S. Thomas, M.A., of Jesus College, and Mr. C. S. Storrs, B.A., of Emmanuel College, were admitted to the degree of Doctor of Medicine; and Mr. G. M. MacDonald to the degree of Bachelor of Medicine and Bachelor of Surgery.

HOSPITAL ABUSE.

(BY OUR SPECIAL COMMISSIONER.)

IX.—FRANCE: UNITED ACTION AND LEGISLATIVE ACTION.[1]

THOUGH the grievances are not so widespread and have not reached so acute a stage as in England, the members of the medical profession in France are also greatly exercised by the question of hospital abuse. Indeed, this trouble together with what we have termed "the Battle of the Clubs," are the two principal reasons which have led to the formation of medical syndicates or unions in different parts of France. It may be said that close upon 25 per cent. of the medical men practising in that country are now in union. The Paris branch of the syndicate is the strongest, for it numbers some 600 members. Dr. Albert le Blond, medical officer of the Saint-Lazare prison for women—which is the lock hospital under the French Contagious Diseases Act—and president of the Paris Medical Syndicate, has devoted much time to the study of the question of hospital abuse. By the courteous invitation of Dr. J. Noir, general secretary of the Paris Syndicate, I was able to be present at a meeting of the executive committee of this organisation, and here I met Dr. le Blond, who furnished me with reports and much information on the question at issue. At the same time I communicated to the committee some details as to the position of affairs in England both with regard to hospital abuse and the battle of the clubs. The members of the committee were delighted to hear that successful efforts had been made in various parts of England to form medical unions. They then requested me to transmit to the medical unions in Great Britain expressions of friendship and fraternity on behalf of the Paris Medical Syndicate. Further they explained that they had established intimate intercourse with the Belgium Medical Syndicate and had had the pleasure of receiving and entertaining in Paris the president and secretary of the Belgian Syndicate, Dr. Vandam and Dr. Cuylitz. They hoped that their relations with the British medical societies would become equally intimate, pleasant, and mutually advantageous. It was their conviction that similar grievances afflicted the medical profession in all parts of the world and that the organisation of the profession into unions or syndicates, both nationally and internationally, was the best means of removing these grievances. To this effect I should add that all communications may be addressed to the general secretary of the Paris Medical Syndicate, Dr. J. Noir, 45, Rue Monge, Paris.

The organisation of the relief of the poor in France differs fundamentally from that which obtains in England. Every phase of public relief comes under the one denomination of L'Assistance Publique—namely, out-door relief to the able-bodied, help or asylums for the aged and infirm or for children, and, finally, hospitals, medical attendance, and medicine for the sick. This is based on the principle that the French nation may be considered as one large family. Each private family is bound by the articles 203, 205, 212, and 349 of the Civil Code to assist its poorer members. But, if the family fails to accomplish this duty, then the Commune, the Department, and the State are each in a measure responsible. The National Assembly has proclaimed that society at large must help its poorer members. The laws of the 19th March, 1793, of the 24th Vendémiaire, year II., and the 22nd Floréal, year II., passed by the National Convention, establish that, in principle, the indigent have a right to public help. Subsequent legislation, however, had tended to weaken rather than to strengthen this principle. Dr. le Blond, in dealing with this question, says that without doubt bread should never be refused to the deserving poor, or a bed in the hospital when sick; but Dr. le Blond cannot admit that misers and those who only pretend to be poor should likewise receive public help. Assistance without discrimination engenders thriftlessness, and Dr. le Blond

declares that the workmen of the large towns already consider the hospital as the ordinary place of refuge when their labour power is checked by even trivial indisposition. There is, perhaps, some exaggeration in this. A strong prejudice against hospitals still survives, especially in the smaller provincial towns. This acts as a natural check and prevents those who can afford to be treated at home from frequenting the hospital. Again, whatever may be the fault of the administration of the relief of the poor in France we in England have always been taught to admire, and if possible to imitate, the thrifty habits of the poorer classes in France. All the writers and social reformers who have dealt with the subject have held up the French people, and especially the French housewife, as examples of order, economy, and forethought. It would indeed be a calamity if the actual methods of poor relief were to undermine such notable virtues. If Dr. le Blond could study the home life of the poorer classes in England he would soon hold a better opinion of the men and women of his own country.

However this may be, there is no doubt that Dr. le Blond, in an address which was delivered to the Paris Medical Syndicate last November, and which, for propaganda purposes, has been printed and circulated, raised a strong point by insisting that what was meant for the poor should be reserved exclusively for the benefit of the poor. The law of the 24th Vendémiaire, year II, article 18, says: "All sick persons with or without legal domicile who are without resources shall be helped either at their domiciles or at the nearest asylum or hospital." To carry out this law the country has been mapped out into medical districts, and lists have been made of persons without means and therefore entitled to medical aid. To admit into hospitals, and in preference to such poor persons, those who, on the contrary, offer payment, has now, however, become a prevalent practice, and this is described as being in antagonism to the spirit of the law. If the object of hospitals is to aid the indigent they should be utilised solely for that purpose. A verdict of the Supreme Court of Appeal (Cour de Cassation), dated Nov. 7th, 1884, declares the gratuitous distribution of medicaments by non-qualified persons to be illegal. This struck at numerous private charities where, notably, unqualified Sisters of Charity dispensed medicaments. On the other hand, the Government introduced a law on June 30th, 1890, authorising the gratuitous distribution to indigent persons of medicine which had been prepared by the dispensing chemists attached to the offices of the administration for the relief of the poor (Bureaux de Bienfaisance). The argument brought forward by Dr. le Blond is that the giving of medical advice should be limited like the giving of medicaments. If the indigent alone are to receive medicaments gratuitously the indigent alone should receive medical advice gratuitously. Why, then, are people allowed to pay for occupying a bed in a hospital? The admission of paying patients must mean the exclusion of pauper patients. In any case this occurs notoriously with regard to pauper patients suffering from phthisis. It is very rare indeed that such patients are accepted in a Paris hospital. The reason for refusing them is that they are too numerous and their cases generally hopeless. Thus there are more than 100,000 patients wandering about in the streets of Paris and spreading the germs of tuberculosis on all sides. If, instead of accepting paying patients, these persons were taken in by special hospitals a source of infection would be removed from the streets and the prevalence of tuberculosis might be very greatly reduced.

The hospitals, however, profiting by decrees which authorised this practice, established a few paying beds. These were at first reserved for persons in needy circumstances who could not afford an expensive home treatment. But the complaint is that this practice has become far too general. The theory in France has now become just the reverse to what it is in England. Theoretically every patient who enters a hospital is supposed to pay, and if he does not do so he must say why. If he does not pay an inquiry is instituted, and if it is found that he is in a good position the bill is presented, and the patient is made to pay just in the same manner as if he had taken a room in a hotel. On inquiry at the Ministry of the Interior concerning this matter it was explained that the patients never refuse to pay, as they shrink from the disgrace a prosecution would entail. All this, however, applies to the middle classes; no workman, no wage earner, is ever expected to pay; but the commercial man, the clerk, &c., if earning a fairly good salary—£200 a year or so—would be made to pay. Most persons in such a position avoid the unpleasantness of an inquiry by at once offering payment, and here the abuse arises. In most hospitals the charge is for medical cases 3 fr. 60 c. per day, and for surgical cases 5 fr. (or 4*s.*). The custom is to pay for a fortnight in advance, the balance being restored if the patient leaves before fifteen days. Now anyone entering a hospital and producing the payment for fifteen days is admitted without further question. Thus, not only persons of limited means, but those who are in the enjoyment of large incomes, are able to gain admission to the hospitals without let or hindrance. Therefore patients who could well afford to be treated at home take up the beds at the hospitals which should be reserved exclusively for poorer people. Nevertheless, this abuse has not been considered sufficiently widespread to justify interference on the part of the municipal council. The question is whether this opinion is based on the real facts of the case or whether it arises from the natural desire of the municipal councillors not to do anything that might vex their electors. But as the majority of electors are poor, and as the abolition of such abuses would be to the advantage of the poor, there does not seem to be much ground to warrant this suspicion. It is nevertheless admitted that abuse exists. The municipal councillors themselves recognise the fact, but they believe that the abuse is not sufficiently widespread to justify interference. Undoubtedly the reputation of the surgeons and physicians attached to the great Paris hospitals is so high that this in itself attracts many persons who, though well off, could not afford the very high fees these same medical men charge their private patients.

With regard to the provincial hospitals it is generally admitted that very little abuse exists. There are but few paying patients in the provincial hospitals. People are too well acquainted with each other, and many persons would not like their friends and neighbours to know that they had been to the hospital. With a view to bringing the same considerations to bear upon the population of Paris, it has now been decided that patients must go to the hospital of their own district, and each district may be considered as a small town in itself. Thus there is more likelihood of neighbours and friends knowing when anyone of their circle goes to the hospital, and this helps to check abuse. In the provinces, there also still survives a strong prejudice against the hospitals. The horrors of a bygone and barbarous age are not forgotten. Tradition is hard to kill, and many country folks fail to realise the improvements that modern hygiene and science have effected. They therefore still look with repugnance upon the hospital and make every sacrifice to avoid going there. It is not like the poor in England, especially the children of the poor who look forward to going to the hospital as a positive treat, a holiday from the squalor, the dirt, the misery, and underfeeding of their own families. How many children have shed bitter tears when brought away from the hospital to return to their wretched homes. In the French rural town the faith in the hospital and the love of the hospital have not yet been engendered, and while the poor continue to shrink in terror from these establishments persons who possess means are still ashamed to go there. The latter, if suffering from some serious complaint, prefer to take a train for Paris, where they hope to find better hospitals, better advice, and where there is less chance of being discovered by their friends and neighbours. In this manner, also, some abuse arises.

It may be said that in official circles the prevalence of hospital abuse in France is not considered as constituting a serious grievance. The old arguments are used as to the difficulty of drawing a line, and it is pointed out that in many cases where, to judge by outward circumstances, a real abuse has arisen a deeper investigation will show that after all the patient was not in a position to remain in his own home. In a word, it is urged that there are other classes beside the labourers and artisans who need the aid that hospitals give, and that a clerk with a frock coat may be just as poor as a workman in a blouse. On the other hand, Dr. le Blond, supported by the majority of the members of the Paris Medical Syndicate, maintains that, on the contrary, the grievance is urgent, is spreading, that a richer class of patients is daily invading the hospitals, to the detriment of the really poor and indigent. The fact that the Poor Relief Administration has, according to official documents, given help for half the accouchements that have taken place in Paris suggests abuse. It is difficult to believe that half the women in Paris are obliged to apply for State aid when about to become mothers.

There is another very ugly feature due to the admittance of paying patients to the hospitals. As they can afford to pay they can afford to give tips to the attendants and the nurses. The poor patients, on the contrary, cannot give gratuities, and consequently they are more apt to be neglected and are not so well served. Therefore the poor patient, perceiving this partiality, takes a dislike to the hospital, will not return, and sometimes aggravates his complaint or even sacrifices his life by remaining outside too long. Dr. de Beurmann, of the Paris hospitals, agrees with Dr. le Blond as to the presence of well-to-do persons in the hospitals, and Dr. Fissiaux urges that often a poor person fails to obtain admittance because the beds are taken up by paying patients. Dr. Chevallereau of the Quinze-Vingts Hospital and Dr. Bimsenstein recognise the existence of these abuses. M. Navarre, municipal councillor, in a report presented to the Paris municipality in 1892, stated that the number of well-to-do patients frequenting the hospitals is increasing, and this opinion was confirmed by another municipal councillor, M. Lyon-Alemand.

At the National Congress on Poor Relief, held at Lyons in July, 1894, Dr. le Blond submitted, on behalf of the Paris Medical Syndicate, the following cases of hospital abuse:—1. Dr. Barré calls attention in the *Médecine Contemporaine* to a lady possessing an income of £800 who went to the Hospital of Saint-Louis to obtain douches that she had been advised to take.[2] 2. One of my patients, whose husband was at the head of a flourishing business, was operated upon for an ovarian cyst at the Lariboisière Hospital in 1892. 3. A woman possessing a large shop took her child very regularly once or twice a week during four months to the Trousseau Hospital for disease of the foot. 4. Dr. ——, of the faubourg St. Antoine, mentions a woman who, though well able to pay, went recently to be operated upon at the Charité Hospital. 5. A gentleman, visited by Dr. J——, notoriously well off, was operated on at the Necker Hospital in Dr. Guyon's clinic. 6. The child of a hairdresser and coiffeur who pays a very heavy rent was operated on for an abscess this year at a hospital. 7. A woman presented herself on Nov. 6th, 1893, at the St. Louis Hospital. She was covered with diamonds and asked for and obtained a consultation from Dr. G——. 8. A person who lives in an apartment in one of the best quarters of Paris, and pays from £200 to £240 rent, was gratuitously vaccinated at the Hôtel Dieu this year. 9. The proprietor of a large shop was operated on for fistula in 1893 at the Charité Hospital. 10. A wine merchant and vineyard proprietor remained three and a half months as a patient at the Bichat Hospital and did not pay anything. 11. A landowner and cultivator was operated on at the St. Louis Hospital in 1889 by Dr. P——, and even took away with him antiseptic solutions and dressings. 12. A patient of Dr. L—— gave up this practitioner so as to go to the hospital to have the actual cautery applied to the spinal region. While undergoing this treatment he bought himself a house for £1800, in which he lives. 13. A man, proprietor of a house in which he lives and where he lets half a dozen flats, was at the Hôpital Cochin for several weeks in 1892-93. 14. A restaurant keeper, owner of a large house, got his mother admitted to the Pitié Hospital on March 23rd, 1893, for a fractured leg. 15. The proprietor of a large brewery, for which he was offered £12,000 last year, caused his wife to be treated at the hospital when she suffered from a burn during the months of February and March, 1893, and sent one of his children to the Hospital of l'Enfant Jésus. 16. A woman, whose husband employs thirty workmen, was nursed at the Pitié Hospital for a wound received on March 1st, 1894. 17. A wine dealer was treated for a long while in May, 1894, for an injured shoulder at the Lariboisière Hospital. 18 Another wine dealer was operated on at the Lariboisière Hospital in February of this year and was an out-patient at the hospital for fifteen days. 19. A woman who paid 4*s.* fees to her usual medical attendant went and obtained advice and medicine at the Lariboisière Hospital in 1893. 20, 21, and 22. A butter merchant, a commercial man, and a pork butcher sent their wives to the lying-in ward of the Lariboisière Hospital on May 13th, June 13th and 16th, where they were delivered.

The third section of the Congress, enlightened by these facts and the assurance that many other similar cases could be mentioned, unanimously passed the following resolution:—"Firstly, the establishments of public assistance having been created so as to help the indigent and the poor—in a word, the disinherited of fortune—must rigorously close their doors against those who merely pretend to be poor. Secondly, that it is necessary to establish a serious control over all persons who ask for help from these establishments, the actual control being quite futile, since it allows those who pay very small sums to enter, though they possess ample means. Thirdly, consequently we demand that the public powers, the Senate and the Chamber of Deputies, should take into consideration a project of law containing the following stipulations:—Clause A. The hospital is reserved exclusively for the indigent, and those who are deprived of all resources. Clause B. Whosoever, being in a position to pay for his treatment when ill, shall have recourse to these establishments, commits an illegal act. Clause C. Whosoever, except in cases of urgency, shall have committed this illegal act shall be condemned to refund all the cost he may have occasioned and to pay a fine of from 4*s.* to 12*s.* If this offence is repeated a further penalty of one to five days' imprisonment may be inflicted."

Such is the position, briefly stated, of affairs in France. It will be seen that the grievance is not so acute, not so widespread, as in England. Nevertheless, the members of the medical profession in France are taking far more decided action. They have been more successful in the forming of a union. In England such bodies as exist are purely local. No attempt has yet been made to bring about a national federation such as those which exist in France and Belgium. Nor has there been any authoritative pronouncement as to what legislation could effect towards bringing about the desired remedies. There is evidently much to be learned on the other side of the Channel; and now that the road is indicated it is to be hoped that more intimate relations will be established between the medical men of France and Great Britain.

THE CONGRESS OF THE GERMAN SURGICAL ASSOCIATION.

(FROM OUR BERLIN CORRESPONDENT.)

THIS Congress was held as usual in Berlin in the week following Easter, and was opened on April 21st, Professor von Bruhns, of Tübingen, being in the chair. The German Surgical Association has now more than 700 members, of whom about 400, including the majority of the leading German, Austrian, and Swiss surgeons, were present. The chairman, in his inaugural address, when enumerating the members of the association who had died during the last twelvemonth, made special reference to the late Sir Spencer Wells, one of its few honorary members. He gave a detailed obituary of the deceased, whom he described as one of the greatest benefactors of humanity, and mentioned that he attended the jubilee meeting of the association.

The Surgical Treatment of Gastric Ulcer.

Professor von Leube, of Würzburg, who had been invited to state his views as a physician, read the first paper brought before the meeting, the subject being the Surgical Treatment of Gastric Ulcer. He said that surgical interference was hardly ever necessary in this disease, and that he had successfully treated about 1000 cases without recourse to surgery. What the patients ought to do is to stay in bed, to use hot poultices, and to drink Carlsbad Water. The poultices must be very hot—hot enough to cause blistering—and they must be changed every ten minutes. The pain usually disappears in about five days, and Priessnitz bandages should then be substituted for the hot poultices and continued for three weeks. Females must not wear corsets. Strict regulation of the diet is indispensable, and Professor Leube gave a detailed account of the dietary system followed in his clinic. The results obtained by this method were very satisfactory. Of all his cases only 2·4 per cent. died; 1·6 per cent. were not benefited, 21 per cent. showed marked improvement, and 75 per cent. were completely cured. Surgical treatment should be resorted to under the following circumstances:—1. When there are repeated hæmorrhages, which make the patient anæmic. It depends on the nature of the individual case whether an operation should be performed or not where there has been only a simple profuse hæmorrhage, for it may be so

Hosted by Google

abundant that surgical aid comes too late. On the other hand, patients often recover from the acute anæmia caused by a single hæmorrhage. 2. When long-continued medical treatment has proved ineffectual to relieve the pains gastro-enterostomy may be tried. 3. When there is perigastritis caused by adhesion of the stomach to other organs, especially when a subphrenic abscess has formed. 4. When there is perforation of the ulcer and an opening into the abdominal cavity. The chances of a perforated ulcer healing are of course very small. Professor von Leube has observed only two cases of recovery under such circumstances. The operation must be performed within ten hours after the perforation. As to prophylactic laparotomy, he considered that there were no prodromal symptoms of impending perforation sufficiently characteristic to be of practical utility. In conclusion, Professor von Leube said that although in the great majority of cases medical treatment unaided by surgery was sufficient, there were nevertheless many patients who would only be saved by the coöperation of the physician and the surgeon.—In the ensuing discussion Professor Miculicz, of Breslau, said that the statistical results of other practitioners were not as good as those of Professor von Leube, and relapses were found to be rather frequent. On the other hand, surgical treatment is now so successful that of the patients operated on only 10 per cent. died. He had cured cases by operation although the symptoms had developed seven and nine years previously. Three methods of operating for gastric ulcer must be considered: (1) Resection, which is the most dangerous method and not very satisfactory, but must be performed when the case is considered to be carcinoma; (2) pyloroplasty, which is a more simple method, but can only be carried out when the gastric and duodenal walls are soft; and (3) gastro-enterostomy, which also gives good results, but sometimes the contents of the stomach penetrate into the ascending limb of the jejunum, and Professor Miculicz therefore recommended that a second anastomosis should be made between the two loops. Speaking of the indications, he said that in cases of adhesion of the stomach to adjacent viscera an operation is necessary to relieve the pain and the adhesions must be separated. In cases of perforation immediate laparotomy is essential. When the patient cannot take an anæsthetic local anæsthesia must be used. With regard to the other indications, Professor Miculicz agreed with Professor von Leube. Operation is, therefore, indicated—(1) when the patient's life is endangered by hæmorrhage, perforation, and inanition; and (2) when prolonged medical treatment has proved useless.

The Successful Treatment of a Wound of the Heart.

Dr. Rehn, of Frankfort, opened a discussion on Wounds of the Heart and their Treatment. After pointing out that penetrating wounds of the heart are rare, and that large lesions cause immediate death while small ones may heal, he went on to state that auricular wounds are more dangerous than ventricular owing to the thinness of the auricular wall. Hæmorrhage, however, is apt to be more profuse when the right ventricle is damaged, and the prognosis in any case depends practically upon the quantity of hæmorrhage. The diagnosis of the site of lesion is difficult to make, but in doubtful cases cautious probing must be performed. The main indication of treatment, Dr. Rehn said, was to keep the patient as quiet as possible, but severe dyspnœa generally precludes this. Venesection has been recommended to check the hæmorrhage. To remove the blood from the pericardial cavity it has been recommended to puncture the pericardium; but as there is risk of inflicting a new lesion it is better to make a long incision and discover the seat of the lesion. Italian surgeons were the first to suggest sutures in these cases, and Professor Rehn has lately been so fortunate as to meet with a case of wound of the heart where by suturing he was able to save his patient. A young man was brought to hospital, having received an injury from a knife in the left side of the chest. There was much dyspnœa and hæmorrhage. As the pericardium became dilated the patient's state became worse and worse. The wound in the fourth intercostal space was then opened up, and after resection of the fifth rib the pericardium was incised. A wound one and a half centimetres in length was then found in the right ventricle. This Dr. Rehn closed by three sutures and packed the pericardial cavity with iodoform gauze. After the operation the pulse and respiration immediately improved, and although the patient's convalescence was retarded by suppurative pleuritis he made in the end a complete recovery.

The Value of X Rays in Surgery.

Dr. Kümmel, chief surgeon to the Hamburg General Hospital, read a paper on the Value of X Rays in Surgery. He said that by the technical improvements in the Roentgen apparatus the x rays have become indispensable to the surgeon. He had made more than 1500 skiagrams, about 500 of which he showed to the meeting. Among these, the most remarkable were those showing Murphy's buttons in the intestines and vesical and renal calculi. Biliary calculi could not be taken by the rays. In almost every skiagram of fracture exhibited the position of the bones was taken before and after setting, proving that in doubtful cases the diagnosis could be verified in this way, while in cases apparently perfectly reduced displacement often was obvious. In fact, however good the position appeared there was almost invariably some displacement. In all diseases of the bones, syphilitic or tuberculous, in osteo-myelitic affections, and in osseous tumours, the x rays had proved useful. In arterio-sclerosis the sclerosed arteries became visible as black stripes on the skiagram. With regard to the therapeutic influence of the rays Dr. Kümmel stated that lupus was improved by an exposure to them of about one hour twice a day. Dr. Hoffa (Würzburg), Dr. Joachimsthal (Berlin), Dr. Oberst (Halle), and Dr. Stachow, of the Army Medical Staff, confirmed Dr. Kümmel's views, and also showed large collections of skiagrams, which will be placed in the library of the Surgical Association.

The Operative Treatment of Prostatic Enlargement.

Professor Helferich (Greifswald) stated that Dr. White, of Philadelphia, was the first to perform castration for this condition, but that the views of surgeons greatly differed as to the usefulness of the proceeding. No decrease of the prostatic gland in respect of the cases after this operation had been noted by one observer, while another reported improvement in about 80 per cent. As an alternative to castration the resection of the vas deferens had been suggested by Dr. Kohler, whose results showed thirty-six cases cured, fifteen improved, and three deaths after this procedure, while thirteen cases showed no alteration. Dr. Bottini's method of cauterisation of the gland and Dr. Bier's plan of ligaturing the common iliac artery gave comparable results. It must, however, not be forgotten, said Professor Helferich, that the condition is liable to spontaneous improvement, while regular catheterisation will relieve the pain. But in grave cases operative treatment cannot be dispensed with.

Dr. Freudenberg (Berlin) then described Bottini's treatment of prostatic enlargement by the galvano-cautery. He said that narcosis was not necessary, an injection of cocaine being sufficient. Nor need the patient be confined to bed; he might get up immediately after the operation, as neither fever nor hæmorrhage occurred. Bottini had successfully treated 43 cases out of 57, and no relapses had occurred. Dr. Freudenberg himself has operated on 5 men, of ages ranging from sixty-three to eighty-one years. Two of them were able to urinate spontaneously three and four hours afterwards respectively.

Professor Socin (Basle) said that in cases complicated by grave cystitis an operation might be tried, but the prostatic gland should then be removed. The value of the "sexual" operations was very doubtful.

(To be continued.)

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Northern Hospital.

THE relief to the electoral committee of the Northern Hospital at the termination of the contest for the honorary physiciancy to the hospital, vacant by the resignation of Dr. James Barr, must have been great indeed, as that body had become fairly bewildered as to the merits of the candidates owing to the persistent attentions and persuasive eloquence of the friends of the latter. There were several candidates for the post, all of whom were highly qualified. The contest, however, lay between Dr. Thomas Bushby and Dr. Charles Macalister, the former being elected by a majority of 9 votes out of an electorate present of 81 members.

Liverpool Medical Club.

The first annual report of the directors presented to the

Hosted by Google

second ordinary general meeting of the club must be considered satisfactory. An analysis of the profit and loss account and balance-sheet is very encouraging when the difficulties inevitable in organising a new concern are considered; upon the whole, therefore, the directors of the club hope that with continued good management and an increased membership a prosperous future is assured for the club. During the year a debating society has been formed and seven very interesting and instructive meetings have been held. The entertainment committee arranged a number of smoking concerts, billiard handicaps, &c., during the season, which have been a great success and the means of bringing the members together socially. The membership of the club now amounts to 112. Dr. Richard Caton, physician to the Royal Infirmary, has been elected President for the ensuing year, succeeding the genial and popular Mr. Mitchell Banks.

Bequests to Local Charities.

The late Mrs. Mary Elizabeth Fishwick, of Liverpool, has bequeathed the following amounts to local charities:—£500 to the Liverpool Hospital for Consumption, £100 to the Liverpool Royal Infirmary, and £100 each to the Eye and Ear Infirmary, Myrtle-street, and to the Liverpool Infirmary for Children. She also made bequests to non-medical charities.

Health of Liverpool.

The medical officer reported that 375 births were registered in the city during the week ending April 24th, representing a birth-rate equal to 30·2 annually per 1000 of the population. The deaths registered during the same period amounted to 304, making a rate of mortality equal to 24·5 annually per 1000 of the population. Of the deaths, 67 occurred in public institutions devoted to the treatment of the sick. The residences of 9 who died in these institutions were outside the city. Of the total deaths, 124 were of children below five years of age; of these, 82 were infants under one year. Among the causes of death, diseases of the lungs accounted for 70 deaths, tuberculous diseases (including phthisis) for 43, diseases of uncertain seat for 7, of the brain, &c., for 38, of the heart, &c., for 23, and of the stomach, liver, &c., for 19. Under the various other classes of disease there were registered 44 deaths. A report of the medical officer of health as to the result of the recently established inspection of Canadian and other horses was submitted to the health committee. The members of the committee said the inspection had been very satisfactory, and the condition of horses now imported had very much improved.

St. Helens Health Committee.

The health committee of the St. Helens corporation have resolved to extend the sanitary depôt at Boundary-road by the erection of a six-cell destructor, &c., at a cost of £8000, and to take in a large plot of land which adjoins the depôt.

Liverpool Anti-vivisectionists.

The Liverpool anti-vivisectionists recently held a meeting in the hall of the Young Men's Christian Association in Mount-pleasant. The following is a specimen of the intemperate language indulged in by one of speakers, a well-known Liverpool public man: "The other day, sir, I was in a very famous university city, or in the suburbs of it, and there drew up a carriage in which was seated a gentleman. I was immensely struck by his countenance and his expression. I said to myself, Who can that man be? He is a remarkable man, a clever man, but if I ever saw a face that seemed to have come out of hell, that is the face; and I was told immediately afterwards that this was a gentleman of renowned fame for his great skill in the practice of vivisection." The gentleman alluded to in the above statement is the reverse of this description and benevolent-looking to a degree; but such are the weapons employed by these unreasonable people.

The Diamond Jubilee Nurses.

The subscriptions towards the amount required for extending the district nursing staff in commemoration of the Queen's Diamond Jubilee, alluded to in THE LANCET of April 24th, now exceeds £10,000.

May 4th.

HOSPITAL REFORM ASSOCIATION.—A meeting of the medical profession and others interested in hospitals will be held in Manchester on May 24th, at 4 P.M.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Health of Newcastle.

THE twenty-fourth annual report of Dr. H. E. Armstrong, the medical officer of health of Newcastle-upon-Tyne, states that the death-rate of the city from all causes for the year 1896 was 18 4 per 1000 population. The number of marriages was 132 more than in the previous year. There were 43 fewer deaths from zymotic diseases. The sanitary authority of the city last autumn added measles and whooping-cough to the list of notifiable diseases, and resolved to admit domestic servants to the hospital for infectious diseases free of charge.

The Newcastle Hospital for Sick Children.

The mayor and corporation, accompanied by the President and members of the College of Medicine, and the Principal, professors, and lecturers of the College of Science, wearing their robes, attended Divine service in Blackett-street Presbyterian Church, Newcastle, on Sunday last, when a sermon was preached in aid of the funds of the Hospital for Sick Children. This is the first time that the Colleges have attended officially any church service except that at the Cathedral.

"The Queen's Shilling."

Under the above heading the *Newcastle Daily Chronicle* invites its readers to subscribe 1*s.* each towards the building fund of the Royal Infirmary, £13,000 of the £100,000 proposed to be raised being still wanting. The *Chronicle* undertakes to collect the shillings and to acknowledge each donation in its columns. The best thanks of the community are due for this kindly action of the proprietor of the paper.

Cyclists and the Diamond Jubilee.

The National Cycle and Motor Car Insurance Company, 33, King William-street, London, E.C., offer to contribute the odd shilling of their guinea premiums to the Newcastle Diamond Jubilee Fund for the rebuilding of the Royal Infirmary. This gift is to be a permanent donation, not confined to the present year; and the shilling is to come from all the policies, not only in this district, but all over the United Kingdom.

Newcastle, May 4th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow University.

MISS M. MACLEAN, M.B., C.M. Glasg., has been appointed Demonstrator of Anatomy in Queen Margaret College, and Miss D. Clark Demonstrator in the botanical laboratory. Mr. W. H. Lang, B.Sc, is the new Lecture on Botany in the College, succeeding Mr. J. C. Willis, M.A, who some months ago was appointed Director of the Botanic Gardens at Colombo. — The class of practical pathology in the Pathological Institute at the Western Infirmary is being conducted by Mr. L. R. Sutherland, M.B. Glasg., Professor Joseph Coats being absent on sick leave. It is satisfactory to know that the latest reports concerning Professor Coats are decidedly favourable, and that his enforced rest is likely before long to lead to the complete restoration of his health.—At a meeting of the Natural History Society, held on the 29th ult., Professor F. O. Bower, D Sc., delivered a lecture on Fixity of Position as a Factor in Plant Life.—The statistics of the preliminary examinations issued by the Joint Board of Examiners show that of 488 candidates in the arts and science faculties in the University of Glasgow 216 satisfied the examiners, and of 81 entrants in the faculty of medicine 37 only passed.

Handsome Bequests.

By the will of the late Miss Martha Brown of Waterhaughs a sum of £97,000 is conveyed to trustees for distribution among various charitable and educational institutions. The West of Scotland Home for Incurables receives £21,000, and a similar sum goes to the corresponding institution in Edinburgh; the Universities of Edinburgh and Glasgow, the Royal Infirmary of Edinburgh, and the Royal Infirmary of Glasgow are each allotted £5000; the Sick Children's Hospital, Edinburgh, and the Western and Victoria Infirmaries,

Hosted by Google

Glasgow, receive £1000 each; and smaller sums are donated to the special hospitals and nursing institutions.

The Proposed West of Scotland Consumptive Hospital.

A further appeal has been made on behalf of this scheme. Donations of £500 and £250 are acknowledged and suggestions for further contributions are made. One of these indicates the necessity for £3000 to build a dispensary in Glasgow, another is for £300 "to provide a sun bath." The objection to the spending of £3000 in the erection of a dispensary on the ground that such an institution will simply come into competition with existing dispensaries and allied organisations has already been indicated in THE LANCET, and a recent correspondence published in the local press shows that this objection at least commands some sympathy. Meanwhile the medical committee understood to be supervising the arrangements makes no sign. The profession and the public generally naturally expect some guidance from the committee, but since Professor Gairdner's letter to THE LANCET announcing the fact that the committee had so far not been consulted silence has reigned supreme. If the committee is still in existence it is surely high time that it either publicly supported the scheme as published or divested itself of further responsibility.

Eye Infirmary, Paisley.

It is announced that in connexion with the Diamond Jubilee, Provost Mackenzie has intimated his intention to present to the town an infirmary to be devoted to diseases of the eye.

May 4th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Children's Hospital, Temple-street, Dublin.

IN aid of the funds of this hospital a fête arranged on a very large scale was formally opened by Her Excellency Lady Cadogan on the 4th inst. There was a very large attendance of the friends and patrons of the hospital and of the general public.

The Mater Misericordiæ Hospital.

The complimentary dinner given by the medical board of the hospital to its football team took place at the Hôtel Métropole, Dublin, on May 3rd. The members of the medical staff, both visiting and resident, were present and numbered, with their guests, somewhat over sixty.

Outbreak of Typhoid Fever.

At the meeting of the City Council, held on May 1st, it was reported that during the previous four months the medical practitioners of Belfast had notified 416 cases of zymotic disease, and of these 289 were typhoid fever, and as Dr. O'Neill (one of the city councillors) pointed out, if the March cases are added, 641 persons had been notified as suffering from this disease during the two months of March and April. The outbreak is principally among young people. It is a question whether there is any real increase in the number of cases, the apparent largeness of the numbers being due to the more correct information obtained by the working of the Notification of Infectious Diseases Act adopted recently in Belfast. The latest returns show that the death-rate of Belfast is 27·9 per 1000, 9·5 for chest affections and 4·6 for zymotic diseases. Numerous suggestions as to the prevention of typhoid fever were brought forward at the meeting of the council, such as boiling the milk and water, &c.; and a conference of all the medical officers was held some time since in reference to this most important question, but the result of the meeting has not yet been made public.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Locomotor Ataxy.

AT the Academy of Medicine a communication was recently made by MM. Gilles de la Tourette and Chipault upon the treatment of locomotor ataxy by stretching of the spinal cord which created much public excitement, being reproduced in the lay journals. These observers, having opened the spinal canal in the dead body and exposed the cord, proved that whilst suspension only results in a trifling elongation forcible curvature of the back produces a very real increase in length, amounting to more than a centimetre. They then applied this treatment of incurvation to forty ataxic subjects. They placed the patient in a sitting position on a table and drew his back forwards until his chin nearly touched his knees by means of a cord passing through a pulley-block fixed to the table and attached to a kind of corset fitting tightly to the shoulders and back of the subject. A dynamometer measured the degree of traction exercised. This treatment was afterwards applied by M. Gilles de la Tourette to forty-seven ataxic patients, twenty-two of whom are said to have experienced a cessation of almost all their symptoms—lightning crises and vesical paralysis among others—and fifteen others to have found benefit from the treatment, while ten remained unaltered. At a subsequent meeting of the Academy M. Blondel made a communication which somewhat dashed the enthusiasm with which the discovery of MM. Gilles de la Tourette and Chipault had been received. He mentioned that he had already published some two years ago a note on the treatment of locomotor ataxy by means of forcible incurvation of the spinal column, and that he had obtained remarkable success in one case where lightning pains had been present, while Erb, in a treatise on ataxia, had pointed out the value of the method. M. Blondel had employed the treatment in five cases and met with one success. He believed that it would succeed chiefly in cases of early disease of the posterior columns where the sclerosis was not too hard to yield to elongation, but that in old cases of sclerosis the effects would be *nil*. He pointed out that the anatomical fact that the cord was lengthened by the process of incurvation had been demonstrated on the dead subject by Bonuzzi.

Surgical Interference in Suppurative Peritonitis.

At the *Société de Chirurgie* a long discussion has taken place upon the rules which should guide surgical interference in cases of suppurative peritonitis. M. Jalaquier had under observation certain cases, one of which healed spontaneously by discharge of a collection of pus through the umbilicus, while of four others one patient was operated upon and died. The virulent agent was the pneumococcus. M. Jalaquier, in reporting upon these cases, objected to the employment of solutions of corrosive sublimate for washing out the peritoneal cavity, preferring to use saline solution. M. Gerard Marchand thought that many cases of peritonitis caused by the pneumococcus assumed the encysted form and that the limitations by adhesions explained the numerous spontaneous cures. The surgeon, he considered, ought not to forget the action of these adhesions, but should make use of them during operation as a ready-formed barrier against the spread of the mischief. It is particularly important to operate before symptoms of toxæmia appear. Pain, distension, vomiting, and scanty urine made a group of symptoms authorising interference. The incision should be made in the middle line. The pus being evacuated and the appendix resected if necessary the peritoneal cavity should be asepticised and drained and all shreds of lymph should be removed. Bleeding points should be compressed immediately, and, finally, iodoform gauze should be loosely packed into the cavity. One drainage tube is sufficient. MM. Rontier Nélaton and Quénu took part in the discussion and laid stress on the difficulty of diagnosis.

A Curious Outbreak of Typhoid Fever.

Professor Laveran has published accounts of several cases of typhoid fever occurring in a military dépôt among the non-commissioned officers. The private soldiers escaped infection and the water used at the barracks was of irreproachable quality. Microscopic examination of the food served to the non-commissioned officers revealed the presence of the bacillus typhosus in abundance on the salad, and the ova of the tænia solium were also discovered on these too generously manured leaves. M. Laveran pointed out, in conclusion, that it was impossible to be too careful in the preparation of uncooked garden stuff for the table, and that this precaution applied especially to strawberries.

Poisoned Fish.

A barge freighted with sulphate of copper has "turned turtle" in the Seine, in the basin of La Villette. Pumps were

Hosted by Google

got to work at once, but the water in the basin became rapidly saturated and a large quantity of poisoned fish soon made their appearance on the surface of the water. Only the strenuous intervention of the police prevented many of the populace from poisoning themselves by carrying away and eating the fish.

The Closing of Two Cemeteries at Versailles.

Two cemeteries have been closed at Versailles, the clayey soil being found quite unfitted for the reception of bodies. Not only were the coffins on inspection found practically unaltered after six years' burial, but the enclosed corpses had for the most part escaped putrefaction.

May 3rd.

ROME.

(FROM OUR OWN CORRESPONDENT.)

International Congress of the Red Cross.

IN time to catch the members of the International Congress of Medicine and Surgery on their return from Moscow, the sixth International Congress of the Red Cross is organised to meet at Vienna. This, it is expected, will be the most important congress of the series. All the Powers, great and small, as signatories of the Geneva Convention, will be represented at its sittings. Italy, who claims to have conceived and planned, if not actually to have "put on wheels," the entire movement, will send the President of her own organisation, the Count Taverna, assisted by the Commendatore Becchi, Counsellor of State, and Dr. Gaetano Mazzoni, Professor of Clinical Surgery in the Roman School. She will also contribute her experience in the Abyssinian campaigns, rich in suggestions for the still further improvement of the ambulance service in mountainous countries. Rome, it will be remembered, from the full reports furnished by THE LANCET[1] at the time, was the scene of the last (the fifth) International Congress of the Red Cross, and it will also be within the memory of its readers from similar reports in these columns that at the International Congress of Medicine, held two years later in Rome, a distinctive feature was the exhibition of Red Cross *matériel*, much of which was tested sooner than was anticipated in the disastrous campaigns aforesaid. These, however, are not the only military operations on a grand scale which have occurred since the rising of the last International Congress. There has been the war between China and Japan, in which the latter (and victorious) belligerent vindicated its right to rank with the civilised Powers by its effective adoption of Red Cross organisation and methods—a step which it followed up by delegating M. Nagao Ariga, its special commissioner, to Geneva, by way of still further putting itself in touch with Western Europe as to the means for alleviating the miseries of war. In the day now passing, moreover, we have the Græco-Turkish campaign and its lessons in Red-Cross intervention, and who knows what further complications may not increase the war area and put the resources of the organisation still further to the test? In the thirty-three years ending July, 1896, there have been on an average sixteen nations engaged in hostilities every twelve months! These statistics were put *en évidence* last year in the interesting brochure illustrating the magnificent Red Cross chart on view at the Geneva Exhibition, and while they dealt with "little wars," such as the Duke of Wellington used to deplore, the lessons they taught as to the necessity for increased efficacy on the part of the Red Cross are driven still further home by the sanguinary outbreaks in the East, notably the Armenian and Cretan butcheries, culminating in the severe fighting on the Thessalian frontier. The programme for the "Conférence Générale des Sociétés de la Croix Rouge" (to give it its official name), which meets next autumn in Vienna, will, it is probable, be unprecedentedly full, even if it does not witness accessions from a quarter unrecognised at preceding Congresses. That quarter, as was shown in a leading article in THE LANCET,[2] is the civilian world, in which calamities on an increasingly extended scale are coincident with the development of industries and the aggregation of masses of workers in ever-augmenting numbers. Proposals have been formulated, principally by the "Congrès International de Samaritains" originating at Vienna, to utilise the resources of the Red Cross for the disastrous mining accidents, railway casualties, conflagrations, to say nothing of floods, famines, and even pestilences, all too characteristic of the nineteenth century, and so to provide for the twentieth a prompter and more effective system of relief than has hitherto been available. These proposals, probably to be renewed at the approaching Congress, are not (as, indeed, THE LANCET showed) regarded favourably at Geneva, and the argument that their introduction would encumber a programme already ample enough for the time may be utilised to shelve them altogether. Still, there is force enough in these said proposals to impress public opinion, and even to make converts to their reasonableness among the nationalities represented at the Congress; indeed, I can vouch for the fact that Italy is prepared to go a considerable way at least in entertaining them and in passing them through the alembic of discussion. If an alliance could be effected by the "civilian" with the "combatant" organisation, and a "grande armée" mobilised for the relief of suffering inflicted on an extended scale, their twofold resources could be placed at the service of either branch, according as circumstances required—the reserves of one being put at the disposal of the other and *vice versâ*. For one thing, the carrying out of the idea would demand much assistance from the medical and surgical profession, and might, as, indeed, THE LANCET indicated, open an outlet for its surplus hands. As I close this letter I learn from a report just handed to me of the General Assembly of the Italian Red Cross (president, Count Taverna) that in spite of the heavy drain of the Abyssinian war the organisation has a balance of 6,000,000 lire, including the value of its *matériel*. It has in the kingdom 360 sub-committees and 109 ladies' sections, with a total of 25,000 members. It possesses 82 transportable hospitals capable of admitting and treating 7000 wounded, and served by 1000 medical officers, pharmacists, and administrative hands, with 2500 men-nurses and helps.

May 2nd.

[2] THE LANCET, Students' Number, Sept. 2nd, 1893, pp. 536-37.

MONTREAL.

(FROM OUR OWN CORRESPONDENT.)

Golden Wedding Celebration.

AN interesting occasion, a few days ago, was the golden wedding anniversary of Sir J. William and Lady Dawson. Mr. Dawson (as he then was) was appointed Principal of McGill University over forty years ago, when it was in a very weak state, the medical faculty being the only section that was at all vigorous. The wonderful growth of the University in wealth and extent is very properly associated with Sir William Dawson's connexion with it. On the occasion of the celebration congratulations poured in upon him and his esteemed lady from graduates from all parts of the world. The various faculties presented costly and beautiful gifts, with addresses expressing the highest sentiments of respect and esteem for the ex-Principal. Sir William Dawson is now enjoying the *otium cum dignitate* of Emeritus Principal of McGill University, and devoting his time to authorship.

Medical Convocation.

At the convocation of McGill University just held seventy-six gentlemen received the degree of M.D. The number of graduates in the class of the first year of Mr. Dawson's Principalship was nine. This is the last year in which medical "capping" will take place in April. The course now consists of four anni medici of nine months, and graduation must necessarily take place at a later date. The immense attendance at meetings of convocation of the medical faculty has quite outgrown the capacity of the old hall of the College, and these meetings have been held "down town". This year's meeting was held in the largest playhouse, which was quite filled. Sir Donald Smith, Chancellor, presided. A most interesting announcement was made during the meeting, that a brother of a deceased professor of physiology had added to his previous benefactions £5000 for a Drake Physiology Memorial. Laval University (French Catholic) in its medical faculty has just graduated thirty-five men; Bishop's College, eight persons, two being women (this is the only medical school which admits women); the Faculty

Hosted by Google

of Comparative Medicine, McGill, thirteen; the College of Dentistry twelve; and the College of Pharmacy twelve.

The Diamond Jubilee.

Various schemes are being discussed for the great celebration here. Many plans of an attractive character have been sketched. The matters of medical interest are a Hospital Jubilee Fund and a Victorian Order of Nurses. This scheme is earnestly and vigorously supported by Lady Aberdeen, the wife of our popular Governor-General. It is not local, but is to be for the whole Dominion of Canada. The particulars have not been given to the public, and, indeed, may not yet be settled in the minds of the proposers. Much correspondence has already appeared in the newspapers, generally favourable to a scheme of this kind, as a permanent memorial of the great event.

British Medical Association.

The meeting of the British Medical Association will be the great medical event of the year. The entire profession is filled with pleasant anticipations of the visit of the many leaders in various departments of medical work who will attend. The Montreal General, the senior hospital, has been receiving attention, extension, and alterations, and will be made as attractive as possible to the medical visitors. The splendid Victoria Hospital will appear at its best. The various committees for the meeting have done an immense amount of work. The committee on invitations has been rather surprised at the number of possible American visitors to the meeting, and a note of warning has been uttered that this is not a pan-medical congress. Some New York journals, fearing the effect of the Montreal meeting on the Philadelphia meeting of the American Medical Association, have flatly stated that they hope no American physicians will attend the British Medical Association unless as the invited representatives of some society or association. There is every reason to believe the meeting will be a great success, although the early anticipations of the large numbers who would attend from England and Europe have been modified somewhat. The committee on exhibits has had a curious experience. A large and excellent hall, the Victoria Skating Rink, was secured and the floor-space laid out in an attractive lithographic plan, and high prices were asked for space, on the supposition that exhibitors would be tumbling over one another in their anxiety to secure places. As, however, there has been no hysterical clamour for space the prices have been brought down. The contractor for the handbook has been disappointed also in the advertising patronage he has been able to secure. This has caused delay, but the book will be issued all the same, and probably during the present month.

Enterectomy and Gastrostomy.

Dr. F. J. Shepherd showed a patient, at a recent meeting of the Medico-Chirurgical Society, an adult male, from whom he had Removed Eight Feet of Small Intestine. The case was one of benignant tumour of the abdomen with extensive adhesions. The patient was in excellent condition.—Mr. Kirkpatrick showed a young woman on whom he had operated for Gastric Ulcer. The patient had been seized while at work with a violent pain in the epigastrium, and was removed to the Montreal General Hospital. Although there was no history of gastric trouble the localised tenderness and suddenness of the attack led to the diagnosis of a ruptured gastric ulcer, and gastrostomy was performed at once. A rupture of the size of a threepenny-piece was found on the anterior surface of the stomach, and the contents of the viscus had escaped. After secure suturing an opening for drainage was made in the abdominal wall lower down, and from this a pint of fluid escaped. The patient made an excellent recovery and left the hospital four weeks after the accident.

April 17th.

SAD DEATH OF A MEDICAL MAN.—A sad death occurred at Uckfield on Sunday last as the result of a bicycle accident. Dr. A. J. Richardson, assistant physician to the Sussex County Hospital, was thrown from his bicycle on Friday, April 23rd, and received injuries causing concussion of the brain and severe lacerated wounds of the face. Until the following Thursday he was progressing favourably, but at that date symptoms of tetanus manifested themselves, and he died at midday on Sunday.

Medical News.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the April sittings of the Conjoint Board held in Glasgow the following candidates passed their respective examinations, those marked with an asterisk (*) passing with distinction:—

First Examination, Five Years' Course.—*John Allan, Glasgow; George Russell Jarvie, Cambuslang; Archibald Buchanan Laidlaw, Glasgow; John Kean, Newry; Frederick C. Willmott, South Africa; John William Dougall, Halifax, N.S.; John Arthur Doyle, Kilkenny; William A. Cole, Lagos, West Africa; John Stewart, Glasgow; William Turner, Glasgow; Robert A. Hamilton, Campbeltown; James S. Colquhoun, Durham; James N. M'Morris, Newfoundland; and David Fyfe, Glasgow.

First Examination, Four Years' Course.—William M. M. Jackson, Brighton; John Robertson, Aberfeldy; Dhanaindranatha Mittra, Bengal; Thomas F. Blake, Andover; and Thomas Marshall Metcalfe, Liverpool.

Second Examination, Five Years' Course.—Duncan M. Macgregor, Oban; Thomas Blane Adam, Glasgow; David Coffey, Ballinahinch; *Joseph Fulton, county Antrim; John George Grant, London; George F. Stoney, Tipperary; Thomas R. W. Atkins, Cork; Lionel R. Popham, Bantry; George Evans, county Londonderry; Alfred Lionel Johnston, Belper; David Scott Russell, Glasgow; and George B. M'Kendrick Overtown, Wishaw.

Second Examination, Four Years' Course.—Louise Fox, India; Richard Brodie, Inverness; Robert J. Morgan, county Antrim; Andrew Dougall, Glasgow; Lilian Edith Sykes, Calcutta; David R. Edwards, Carmarthen; Patrick William M'Hugh, Enniskillen; Alfred B. S. Powell, Kingston-on-Thames; Charles Abbott, Leeds; Daniel Patrick G. O'Sullivan, Cork; Reginald Cecil M. Hoare, Aston, Birmingham; and Frank Hart B. Gaden, Queensland, Australia.

Third Examination.—*Richard Staward, Northfield; Edward H. Harrison, Belfast; William Carey, Haywood; Abraham J. B. Albertyn, Cape Colony; Henry A. Marquis, Lancashire; Robert Mackie, Glasgow; and William Hutton, Greenock.

Final Examination, and admitted Licentiates of the three co-operating authorities.—Charles Frederick Spinks, Maryhill; George Harper Pearce, Redcar; William B. K. Richards, Ross, Herefordshire; Edmund P. Hewitt, Edinburgh; Albert Ernest Blades, Derby; Reginald P. H. Whitmarsh, Brighton; Benjamin Wade, Pudsey; Alexander Kennedy, Ayr; Jane Boyes, Glasgow; Allan Edgar Hawkins, Portobello; Alexandre da Fonceca Dias, Portobello; John William Mackay, Trinity; and James Hamilton Stuart, Edinburgh.

UNIVERSITY OF CAMBRIDGE.—Third M.B. and B.C. Examination, Part I. (Surgery and Midwifery). The following have been examined and approved:

Allfrey, B.A., Trinity; R. H. Bell, B.A., Trinity; Coleman, B.A., St. John's; A. W. Daniel, B.A., Emmanuel; Deller, B.A., Trinity; Forbes, B.A., Christ's; Grey, B.A., Trinity; Gregory, B.A., St. John's; Harrison, B.A., Magdalen; Heilborn, B.A., Caius; Irving, B.A., Caius; Jephcott, B.A., Caius; Lindsay, B.A., Sidney; W. F. Lloyd, B.A., Clare; Lowe, B.A., Jesus; Mathias, M.A., Christ's; E. A. C. Matthews, B.A., Trinity; H. D. O'Sullivan, B.A., Emmanuel; Prest, B.A., St. John's; Roderick, B.A., Emmanuel; Rowland, B.A., Downing; B. H. Slater, B.A., Trinity; C. White, B.A., Christ's; E. A. Wilson, B.A., Caius; W. R. Wilson, Corpus; and Yeld, B.A., Trinity.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the Convocation held on April 24th the following degrees were conferred:—

Doctor in Medicine.—James Arnott, M.B., B.S. Durh.; Edward James Brewis, M.B., B.S. Durh.; Henry Fawcett, M.B., B.S. Durh.; Charles Gilbert Burrington Kempe, M.B., B.S. Durh., M.R.C.S. Eng., L.R.C.P. Lond.; Cuthbert Umfreville Laws, M.B. Durh., M.R.C.S. Eng.; William Martin, M.A., M.B., M.S. Durh.; William Ernest Peacock, M.B., B.S. Durh.; William Harland Peake, M.B., B.S. Durh., M.R.C.S. Eng., L.R.C.P. Lond.; James Atkin Henton White, M.B., B.S. Durh., M.R.C.S. Eng., L.R.C.P. Lond., F.R.C.S. Edin.; and Francis James Worth, M.B., B.S. Durh., M.R.C.S. Eng., L.R.C.P. Lond.

Doctor in Medicine (practitioners of fifteen years' standing).—Joseph Hamilton Balfe, L.R.C.P. and S. Edin.; John Cahill, F.R.C.S. Eng.; Henry Clarke, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A.; Edward Cluneglas Davies, M.R.C.S. Eng., L.R.C.P. Lond.; Robert Hugh Hodgson, M.R.C.S. Eng., L.R.C.P. Edin.; Sydney Robert Lidiard, M.R.C.S. Eng., L.R.C.P. Edin.; and Francis Wm. Sutton, M.R.C.S. Eng., L.S.A.

Bachelor in Medicine.—John Charles Anderson, London Hospital; Mervyn Alexander Archdall, College of Medicine, Newcastle-upon-Tyne; John Joseph Foster, M.R.C.S. Eng., L.R.C.P. Lond., Guy's Hospital; Thomas Harold Gibbs, Alfred Phillips Lloyd, John Lowry, Daniel Wells Patterson, Albert Garthorne Widdowfield Pearson, and William Simpson, College of Medicine, Newcastle-upon-Tyne; Charles Seaver Smith, Mason College, Birmingham; Robert Alfred Wilson, College of Medicine, Newcastle-upon-Tyne; John Hutchinson Wood, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; and Thomas Woodman, College of Medicine, Newcastle-upon-Tyne.

Bachelor in Surgery.—Mervyn Alexander Archdall, Richard Henry Bellwood, M.B. Durh., Thomas Harold Gibbs, Wilfred Robert Kingdon, M.B. Durh., John Lowry, Daniel Wells Patterson, Albert Garthorne Widdowfield Pearson, and William Simpson, College of Medicine, Newcastle-upon-Tyne; Charles Seaver Smith, Mason College, Birmingham; Robert Alfred Wilson, College of Medicine,

Hosted by Google

Newcastle-upon-Tyne; John Hutchinson Wood, St. Bartholomew's Hospital; and Thomas Woodman, College of Medicine, Newcastle-upon-Tyne.

Bachelor of Hygiene.—John Stratford Hall, M.B., B.S. Durh.; James Henry Hunter, M.D., B.S. Durh.; and Peter Robert Ingram, M.B., C.M. Aberd.

Diploma in Public Health.—Frederick Smith, L.K.Q.C.P., L.R.C.S. Irel.

MEDICAL MAGISTRATE.—Mr. Fred. J. T. Sawkins, M.B., Ch.M. Syd., medical superintendent of the Prince Alfred Hospital, Sydney, has been appointed a Justice of the Peace for New South Wales.

CHURCH SOCIETY FOR THE PROMOTION OF KINDNESS TO ANIMALS.—The Dean of Winchester presided at the fourth annual meeting of the Church Society for the Promotion of Kindness to Animals held recently, by permission of the Duke of Sutherland, at Stafford House. Letters of regret at inability to attend from fourteen English and three colonial bishops and from many others were laid upon the table. A resolution in favour of further legislation respecting slaughter-houses and an enactment whereby the title "domestic" in the Prevention of Cruelty Acts be made to include all animals placed in confinement was moved by Colonel Barrington Foote, seconded by the Rev. A. H. A. Smith, and carried. A resolution urging ladies to give up the wearing of feathers in cases where the procuring of them involved cruelty was proposed by Mrs. Lemon, hon. secretary of the Society for the Protection of Birds, seconded by General Lowry, C.B., and carried. A discussion on the muzzling of dogs ensued, and ultimately the following resolution was adopted: "That in the interest of animals the muzzling order should be extended to the whole of Great Britain and Ireland, accompanied by quarantine and subsequent registration." Votes of thanks to the Duke of Sutherland and the chairman closed the proceedings.

PRESENTATIONS TO MEDICAL MEN.—Mr. Conolly Norman, F.R.C.P., F.R.C.S. Irel., resident medical superintendent of the Richmond District Asylum, Dublin, at a largely-attended meeting of the staff, several governors, and medical friends, held in the dining-hall of the institution on April 27th, was presented with a beautiful illuminated address by the staff of the asylum, on the occasion of his resuming duty after a long illness. At the same time Mrs. Norman was the recipient of a present of silver as a small memento of the occasion.—Mr. Wm. Gardner, L.R.C.P. Lond., M.R.C.S. Eng., on leaving the Warwick County Asylum at Hatton recently, was the recipient of a handsome silver centre bowl and cigarette-case, the gift of the nurses and attendants. Dr. A. Miller, the medical superintendent, in making the presentation on behalf of the nursing staff, said that although Mr. Gardner had been amongst them only a short time, he had endeared himself to all by his kindliness of manner, and would take away with him the good wishes of all for his future welfare.—The members of the St. John Ambulance Classes at Brockhampton, Gloucestershire, have recently presented Mr. William Cox, M.R.C.S. Eng., M.S.A., of Winchcombe, with a silver revolving breakfast dish as a mark of appreciation of his services as honorary lecturer.

MUNICIPAL LODGING-HOUSES.—Two schemes have been submitted by the borough engineer to the corporation of Southampton for the proposed dwellings to be erected on the slum area which has just been cleared. The first scheme suggested a lodging-house for 297 nightly lodgers, no provision being made for families. The cost of this was put at £23,146 10*s*, or £1104 4*s*. 8*d*. annually. The second scheme allows for a lodging-house to cost £14,066, or £642 12*s*. yearly, and another block to be used as artisans' dwellings, and estimated to cost £7080 10*s*., or £323 19*s*. 8*d*. yearly. The second named lodging-house would take 216 nightly lodgers and the artisans' dwellings would be on the lines of those erected by the London, Manchester, and Sheffield Railway Company in St. John's Wood. The medical officer reporting on the matter recommended the second scheme. He said he had calculated that the first would mean an annual loss of £229 4*s*. 8*d*.; the second a yearly profit of £324—£274 on the lodging-house and £50 on the dwellings. He added: "I am bound to state that I cannot explain why the buildings do not show a greater profit, as buildings which have been erected at other places show large profits; the only conclusion I can come to is that the estimate for the buildings must have been made on a liberal scale." The second scheme has been practically adopted by the corporation.

GERMAN HOSPITAL, DALSTON.—The fifty-second annual dinner in aid of the German Hospital, Dalston, was held at the Hôtel Métropole on April 30th. The chair was taken by the Duke of Cambridge, the President of the hospital, who said that an addition of ten beds had been made to the accommodation provided for female patients, and that the children's wards had been much improved. Alterations in the sanitary and lighting arrangements were much required, and for these an outlay of £3000 would be necessary. The benefits of the hospital were by no means restricted to patients of German nationality, many of them, both in-patients and out-patients, being English residents in the vicinity. During the evening a selection of music was performed by Madame Marchesi, Herr Johannes Wolff, and others. The secretary announced a list of subscriptions and donations amounting to £3300, including £250 from the German Emperor, £50 from the Emperor of Austria, £100 from Baron Schröder, and £20 from the President.

THE NEWPORT (MON.) WATERWORKS.—Some uneasiness is felt at Newport with regard to the position of affairs at the new waterworks at Wentwood, which are situated about eight miles from the town. A considerable amount of opposition was originally raised to this site, but the corporation, acting upon expert opinion, let the contract to a Glasgow firm for £95,596. When the work was in progress, however, it was found that the puddle trench had to be sunk much deeper than was at first anticipated, and as this would involve a large additional outlay the corporation obtained fresh advice, the result being that one expert was averse to the work proceeding, while another recommended the corporation to proceed with the work themselves, advising that concrete be added to the reservoir to give additional security. This latter advice was followed, and the original contract was mutually cancelled. For about twelve months the work has been conducted by the corporation, the trench being sunk about 100 ft. A few days ago a test of the puddle trench was made, when it was found that the water oozed in an unsatisfactory manner. The waterworks committee, at their meeting on April 28th, acting upon expert advice, decided to have further tests made, when it is hoped that more satisfactory results will be obtained.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 21st, Mr. Chicken being in the chair.—Dr. Porter read a paper on the Relation of Dentistry to General Practice, in which he said that although many medical men consider they are in no way responsible for the care of their patients' teeth, they can often save patients from the effects of their own ignorance, as, for instance, by urging the necessity of a periodical examination of the teeth; this is especially true in regard to the teeth of children. The pathology of dental caries was briefly discussed to show that it was not in any sense of the word an inflammation. In considering the immunity of certain persons from dental caries, Dr. Black's recent experiments were quoted as showing that it did not necessarily depend upon the density or percentage of lime salts contained in the teeth. The preventive treatment of caries was shown to consist chiefly in a strict attention to oral hygiene and extraction in overcrowded mouths, constitutional remedies being of no direct practical value. General anæsthesia in dental operations was the next question discussed. It was pointed out that for the great majority of such operations nitrous oxide fulfilled all requirements. Should prolonged anæsthesia be necessary the preference was given to nitrous oxide followed by ether. The use of chloroform was strongly deprecated, statistics being given to show the high percentage of deaths from the use of chloroform in dental operations. In conclusion, the severe constitutional symptoms attending alveolar abscess were mentioned, their true cause often being overlooked.—Dr. Hunter showed a stereoscopic photograph of a patient suffering from an Aneurysm of the Femoral Artery.—Dr. Tresidder showed for Dr. Marshall a photograph of a hand showing Onychomycosis. The patient was a boy who had suffered from ringworm of the scalp for years.—Mr. Chicken showed a chart of the temperature of a patient suffering from Diphtheria. Various local applications were used at first with apparently no effect, but eucalyptus oil produced an immediate and marked lowering of the temperature. The pure oil was used and freely painted on the throat. Mr. Chicken also exhibited a skiagraph showing a Coin impacted in the Œsophagus.

Hosted by Google

ROYAL INSTITUTION.—The annual meeting of the members of the Royal Institution of Great Britain was held on May 1st at the house of the institution in Albemarle-street, Sir James Crichton Browne, M.D. Edin., F.R.S., treasurer and vice-president, presiding. The annual report of the committee of visitors for the year 1896, testifying to the continued prosperity and efficient management of the institution, was read and adopted. The following gentlemen among others were unanimously elected as officers for the ensuing year :—President: The Duke of Northumberland. Treasurer: Sir James Crichton Browne. Secretary: Sir Frederick Bramwell, Bart. Managers: The Right Hon. A. J. Balfour, Lord Lister, Mr. William Crookes, Mr. Edward Frankland, Dr. Donald W. C. Hood, Mr. Victor Horsley, Mr. William Huggins, Dr. A. W. Rücker, and Sir Henry Thompson. Visitors: Dr. W. A. Brailey and Sir Francis Laking.

DIPHTHERIA IN LONDON.—The deaths registered as due to diphtheria in London last week were identical in number with those registered in the week preceding—namely, 40. In the four weeks ended on May 1st the registered deaths have been 23, 30, 40, and 40, the latter being 8 in excess of the corrected decennial average for the seventeenth week of the period 1887–96. Three of the 40 deaths were of infants under one year of age; 23 others occurred in children aged from one to five years; and 3 were of persons aged over twenty years. Lambeth was credited with 5 deaths, and Hammersmith, St. Pancras, Hackney, Shoreditch, and Poplar sanitary areas were respectively credited with 3 deaths. The admissions to hospitals in the week numbered 102, against 103, 83, and 96 in the preceding three weeks; and 767 patients suffering from diphtheria remained under treatment on May 1st. In the outer ring of London there were last week registered 9 deaths from the disease, of which 3 occurred in Brentford, 3 in Edmonton, and 2 in West Ham districts.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Plumbers' Registration Bill.

THE House of Commons, at its sitting on Friday, April 30th, gave a second reading to the Plumbers' Registration Bill and referred the measure for further consideration to the Grand Committee on Trade. The Bill provides for the examination and registration of plumbers, and while creating no monopoly seeks to prevent unqualified men representing themselves as registered.

Public Burial Grounds.

The House of Commons, on the motion of Mr. J. W. Sidebotham, has decided to appoint a Select Committee to inquire into the subject of burial grounds provided by local authorities, whether any alterations in the existing law are necessary, especially in regard to the consecration of the ground, the provision of chapels, the allocation of fees, and the appointment of chaplain.

Budget Figures.

As usual, in making his Budget statement the Chancellor of the Exchequer gave some account of the food and drink consumed by the people of these islands during the year. As testifying to the prosperity of the country he said that during the past year our people have smoked and drunk more, have earned more money and paid more Income Tax, have written more letters and have paid more Death Duties. The receipts from Customs last year were £21,254,000, or £498,000, representing 2·4 per cent., above the receipts of 1895–96, the estimated increase of the population in the year being 0·8 per cent. The two groups of coffee and dried fruit showed a trifling improvement, which was, he feared, not likely to be maintained owing to the war in the East. Foreign spirits produced a net revenue of £4,316,000 or £99,000 more than in 1895-96. This was due to an increase of £125,000 in the receipts from rum, which, said Sir Michael Hicks Beach, was a most unaccountable article. It had been a favourite Customs theory that the receipts from rum went up as the thermometer went down, but considering the temperature of last winter he did not think that that theory could be maintained. Tea had produced £3,800,000, or £54,000 more than in 1895–96; tobacco £11,013,000, or £265,000 more than in 1895–96; and wine £1,295,000, or £40,000 more than in 1895–96. This increase in wine, he said, was a novelty of recent years. He believed it was mainly due to the increased duty which was imposed some years ago by Mr. Goschen upon sparkling wines. The taste for what was erroneously called champagne was very largely increasing. Coming to Excise, the Chancellor of the Exchequer said that the receipts amounted to £27,460,000, or £690,000 more than in 1895-96. Beer showed an increase of £181,000 and spirits of £434,000.

Treatment of Habitual Offenders.

On Tuesday, May 4th, in the House of Commons, Sir Charles Cameron moved, and Dr. Farquharson seconded, a resolution in favour of the institution of adult reformatories for the special treatment of habitual offenders and misdemeanants on the lines recommended by the Departmental Committee which inquired into this subject in Scotland. Sir Charles Cameron addressed the House at some length in support of the resolution, but Dr. Farquharson had not got far with his speech when the attention of the Speaker was called to the fact that there were less than forty members present, and the House was counted out. Consequently no decision was arrived at on the subject.

Public Health (Scotland) Bill.

The Grand Committee on Law of the House of Commons began on Tuesday, May 4th, the consideration of the Public Health (Scotland Bill, and at the end of a long sitting had got through five of the sixty-three pages of amendments. There was some debate as to the qualifications to be required of medical officers in burghs, in which Sir William Priestley and Sir Charles Cameron took part. The upshot of the business was a compromise allowing men without a particular diploma to be appointed only with the express consent of the Local Government Board.

HOUSE OF COMMONS.

THURSDAY, APRIL 29TH.

Vivisection Certificates.

Mr. Weir asked the Secretary of State for the Home Department if he would state the number of persons in England, Scotland, Ireland, and Wales respectively licensed to practice vivisection, and how many of them held certificates to dispense with anæsthetics.—Sir Matthew White Ridley replied that the number of persons licensed at the present time in England was 145, in Scotland 52, and in Wales 1; the number holding the certificate dispensing with anæsthetics was in England 86, in Scotland 30, and in Wales none. The only figures in his possession as regards Ireland were those for 1895; in that year the number of licences was six, of whom one held a certificate dispensing with anæsthetics. In giving the hon. Member these figures he might remind him that the certificate in question was never given for operations involving serious pain, but only for such operations as inoculations or hypodermic injections.

Dog Muzzling.

Mr. A. Drucker asked the President of the Board of Agriculture whether he was aware of the fact that the majority of local bodies had not adopted the system of muzzling dogs recommended by the Departmental Committee, and also that many recognised authorities were against such compulsory muzzling; whether the said Committee took steps to ascertain the views of well-known breeders before making their report; and if, considering the fact that muzzling entailed serious inconvenience upon the owners of dogs and grave injury to the health of the animals, he would facilitate further inquiry.—Mr. Walter Long said, in reply, that he found it somewhat difficult to understand what his hon. friend meant by his first question, inasmuch as the Departmental Committee recommended that muzzling orders should be made in future, not by local, but by central authorities. He was aware, of course, that compulsory muzzling did not commend itself to everyone, but the question was fully discussed from all points of view before the Committee, who also took evidence from breeders. This being the case, he could not assent to the suggestion that further inquiry was necessary.

Death from a Bite of a Cat.

Mr. Duncombe asked the President of the Board of Agriculture whether his attention had been called to the death of Mr. John Hetch, sixty years of age, who died in the Queen's Hospital, Birmingham, from the effects of a cat's bite; whether he was aware that the medical evidence proved the death to be undoubtedly the result of rabies; and whether he was prepared, either by issuing a universal muzzling order for cats, or otherwise, to guard against the danger thus shown to exist.—Mr. Walter Long said that his attention had been called to this lamentable case, which seemed undoubtedly to have been one of hydrophobia due to the bite of a cat. He did not think that any direct action against rabies in cats was either practicable or necessary. The information in his possession went to show that the disease was usually conveyed from dogs to cats, not *vice versâ*, and, in fact, no cases under the latter head were known to him. If, therefore, they succeeded in their efforts to stamp out rabies amongst dogs in this country the disease was not at all likely to be kept alive by means of cats. He might, perhaps, add for the assurance of owners of cats that out of 1075 persons treated for hydrophobia at the Pasteur Institute during the first nine months of 1895 1039 had been bitten by dogs and only 36 by cats.

London Water Question.

Mr. Chaplin announced that the names of the members of the Royal Commission on the Water-Supply of London are as follows:—The Right Hon. Lord Llandaff, chairman; the Right Hon. J. W. Mellor, M.P., Sir John Dorington, M.P., Sir G. B. Bruce, C.B., Major-General A. de Courcy Scott, R.E., Mr. A. de Bock Porter, C.B., Mr. H. W. Cripps, Q.C., and Mr. Robert Lewis. The right hon. gentleman added that he hopes to bring in the promised Bill dealing with the water question as soon as he sees any prospect of making progress with it.—Mr. Broadhurst asked Mr. Chaplin whether he would consider the desirability of taking such action as might be necessary to prevent any one local authority monopolising the sources of water-supply from the great watershed of the country in order to ensure equal opportunity for all communities to avail themselves of a share in this great and natural necessity of the people.—Mr. Chaplin said he was not aware that any local authority was seeking to monopolise the sources of water-supply from the great watershed of the country, nor was he quite clear as to what watershed it was that the hon. Member referred to; but such a scheme as that suggested would require express Parliamentary powers, and he had no doubt that Parliament would give any such scheme very careful consideration before assenting to it, and would have due regard to the interests of communities other than those of the authority by whom it was proposed that the water-supply should be appropriated.

Mr. Woods asked Mr. Chaplin, in view of his promise to introduce a measure this session for the purpose of strengthening and improving the position of the water consumers of the metropolis, whether he was aware that the East London Waterworks Company had introduced a

Hosted by Google

new condition in their latest demand notes—viz., that it will be unlawful to use water in the future for garden use except through meters; whether in his promised measure he would make provision protecting the consumers against this prohibition of the use of water in gardens; and if he was aware that the company in question had admitted that no reliable water meter had yet been invented.—Mr. Chaplin said he was informed by the company that, owing to the excessive use and waste of water by reason of garden hose and other apparatus being employed and frequently left running day and night, the directors had given notice for determining the arrangements entered into for garden supply. The fixed charge had been abolished, and the supply for garden purposes would be furnished through meters. He must defer any statement as to the provisions of the proposed measure until it was introduced by him. As regards the last question, the company stated that they were not aware that they had ever "admitted that no reliable meter has yet been invented." They also stated that it was physically impossible for more water to be registered than passed through the meter, although it might happen that the whole of the water passing through the meter was not registered.

FRIDAY, APRIL 30TH.

Vaccination Commission.

Mr. T. W. Russell, in reply to a question addressed to him by General Laurie, said he was informed that the appendices to the report of the Royal Commission on Vaccination were now in the printer's hands, and would be issued as soon as the lithographs accompanying them were ready.

Salt for the Navy.

Sir Charles Cameron asked the First Lord of the Admiralty whether it was the case that salt was not included among the condiments issued by the Admiralty for use on board ship; and whether, considering the importance of salt as a dietetic ingredient, and the fact that the use of salt meat as the principal form of food on board ship had long been superseded, he would consider the propriety of issuing salt as well as mustard and pepper for use on board Her Majesty's ships.—Mr. Macartney, Financial Secretary to the Admiralty, replying to the question, said that salt had hitherto been issued as a ration only in the case of boys in training ships and troops on passage where the "savings" system did not exist. His attention was only drawn to this after the Estimates for the current year were framed, but arrangements were now being made which would meet the views expressed in the hon. Member's question.

Plague on Board Ship.

Sir Walter Foster asked the President of the Local Government Board whether the Indian transport, *Dilwara*, which arrived at Southampton on April 6th, had had a fatal case of plague on board during her voyage; whether the local authorities found their sanitary powers sufficient to protect the local health interests; and whether this was the second occasion within the last few months on which the infection of plague on board ship had been successfully dealt with in this country without any resort to quarantine detention of vessels and persons.—Mr. T. W. Russell, replying for Mr. Chaplin, said that a fatal case of plague occurred on board the Indian transport, *Dilwara*, after the vessel had left Bombay. The body was buried at sea, and under the recent Venice Convention only the two actual attendants on the sick person were detained at Suez (Moses' Wells), the vessel at once passing through the canal in quarantine. On reaching Southampton on April 6th the *Dilwara* was met by a medical inspector of the Board, who acted in concert with the military and local port authorities. No further case had occurred, and under the excellent arrangements organised by the port medical officer all the 1235 persons on board were allowed to land, and the existing powers were found to be fully sufficient to protect all health interests concerned. The hon. Member was quite correct in his assumption; this was the second occasion within the last few months on which the infection of plague on board ships had been successfully dealt with without resort to any quarantine detention of either vessels or persons.

Overcrowding on Railways.

Mr. Ritchie, President of the Board of Trade, said, in reply to Mr. Weir, that he saw no reason to appoint a committee to inquire into the means to be adopted to prevent the overcrowding of railway carriages.—Mr. Weir thereupon intimated that he would call attention to the matter on the Estimates.

MONDAY, MAY 3RD.

The Stamping Out of Rabies.

Mr. Walter Long, President of the Board of Agriculture, replying to a question by Mr. Lough, said it was not proposed to apply muzzling orders to the whole country, but only to areas in which rabies undoubtedly existed or to which there was reasonable fear that it might have been conveyed. A series of orders for this purpose would be issued in the course of the next few days. No particular pattern of wire muzzle was compulsory, but with a view to assist dog-owners in the selection of a muzzle specimens of a muzzle which the Board believed to be both efficient and humane would be deposited at the principal police stations in districts to which muzzling orders were applied. An order regulating the importation of dogs would be issued almost immediately. It would be premature for him to forecast the time during which it would be necessary for muzzling orders to be kept in force. Rabies was, unfortunately, a disease which might be dormant for a considerable period after an animal had been bitten, and much would depend upon the support the Board received from local authorities and dog-owners generally in their efforts to stamp out the disease in this country.

BOOKS, ETC., RECEIVED.

BAILLIÈRE, J. B., ET FILS, Paris.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

TRICHOMONAS VAGINALIS.

Dr. N. S. DAVIS, of Chicago, describes a case in which the urine of a female patient was found on many occasions to contain moving amœboid bodies, mostly of oval shape. When in motion the forward end was generally narrowest, and from it projected several rapidly moving cilia. When dead these objects were occasionally oval but were more often round. They were clear and homogeneous in appearance, and might easily be mistaken for unusually clear, oval or round epithelial cells. They were found in large numbers in scrapings from the vagina, from the labia minora, and from the meatus urinarius; in these scrapings they retained life much longer than in the urine. They could be readily stained by aniline dyes, especially methyl-blue, and an oval nucleus could then be seen in many, but not in all. They had on an average about two-thirds the length of a squamous epithelial cell from the external genitals, but they were not so broad. The cilia were from one to one and a half times the length of the amœboid body. The patient suffered from nephritis and mild glycosuria; no symptoms were observed which could be ascribed to the trichomonas; the vulva was moist, clean, not reddened, and not in any way abnormal; the urine contained epithelial cells in unusual numbers.

M.R.C.S.—No final decision has been come to with respect to the reproduction of Lord Lister's portrait. Nothing can be done until the picture returns from the Royal Academy to the Royal College of Surgeons of England in August.

X. Y. Z.—We do not know whether the Red Cross Society needs any medical officers for Greece at the present time. Our correspondent might address the Greek Legation, 58, Scarsdale-villas, Kensington, W.

Mr. W. G. Earle is thanked for his communication.

"WANTED A HOME FOR AN IMBECILE BOY."

A CORRESPONDENT writes: "In reply to Mr. Barnley's query as to a training home for a boy of deficient mental condition, may I suggest that if certifiably imbecile he might be received at the Midland Counties' Idiot Asylum, Knowle, near Birmingham, on a moderate annual payment, the amount of which could be learned from the secretary, Mr. W. G. Blatch. If the mental deficiency be of but slight character, application might be made to Miss Paul, 27, Percy-street, London, W., secretary of the National Association for Promoting the Welfare of the Feeble-minded, which is about to start a home for boys."

F. W.—An occasional occurrence of the kind our correspondent mentions need give him no uneasiness whatever, and the step he is about to take is quite justifiable.

"DR. RENTOUL'S EXPENSES FUND."—SIXTH LIST.

To the Editors of THE LANCET.

SIRS,—I enclose the final list of subscriptions to the above fund. It will be seen that the net result falls short of the sum asked for (£109 18*s.* 5½*d.*) by about £6. I beg to thank the subscribers to the fund, especially those who by their helpful letters proved to me that Dr. Rentoul has at his back a considerable number of practitioners who are willing to work and give for the cause of professional reform. I wish also to thank Mr. Colin Campbell, of Saddleworth, Yorks, and Dr. J. L. Speirs, of Gateshead, who have examined my accounts and certify them to be correct. With thanks also to yourselves, who have enabled me to give publicity to this fund.

I am, Sirs, yours faithfully,

ALFRED COX, M.B. Durh., Hon. Sec. and Treasurer.

Gateshead, May 4th, 1897.

Nemo.—In such cases as that mentioned by our correspondent, where the pelvis is normal, any difficulty that may arise in the way of prolongation of the labour is more likely to be due to rigidity of the soft parts. Even if any drug could be relied upon to relax the pelvic articulations the possibility of rigidity of the soft parts would still remain. In many elderly primiparæ, however, the accoucheur is agreeably surprised to find that labour progresses favourably and that the patients' forebodings are not justified by the event.

THE "RELIANCE" PERSONAL WEIGHING MACHINE.

THE illustration shows a new and cheap form of personal weighing machine sold by Messrs. Arnold and Sons of West Smithfield for 21*s.* This machine can be readily put out of the way when not wanted,

as it can be placed under a chair or in a cupboard. Hitherto these personal weighing machines have taken up too much space in a consulting room and the expense has been too great. This machine weighs up to 24 st., and being very light and portable can be used upon the floor or placed on a chair. It is very simple in construction and not likely to get out of order. The size of the platform is 10½ in. by 13½ in., with brass steelyard slide and weights. The whole machine is neatly japanned.

"MR. DAVENPORT AT PORTSMOUTH."

The above is the title of an article which has been sent to us by a correspondent, who says that it was cut from the *Portsmouth Times*, of May 1st. We think that our contemporary deals hardly by its readers in devoting space to the glorification of a quack; but the article contains passages which reveal so clearly the true nature of the man whom it purports to puff that the whole thing may be a piece of journalistic irony. "In the course of his (Mr. Davenport's) studies," it runs, "he devoted special attention to typhoid fever, and during the alarming illness of the Prince of Wales from that terrible disease in 1871, Mr. Davenport laid before the physicians in attendance on his Royal Highness suggestions and remedies for the distinguished patient's cure. The receipt of these was duly acknowledged in a letter forwarded from Sandringham, which our representative saw." It would have been more honest if "our representative" had pointed out to the readers of the *Portsmouth Times* what was certainly the case—that the formal act of acknowledgment of a communication does not imply any interest in the communication. All sorts of troublesome persons pestered the Prince's attendants with foolish suggestions at that time, but Mr. Davenport is, as far as we are aware, singular in attempting to make money out of the courtesy which preferred not to allow him, however meddlesome his act, to remain unanswered. In another place the article states that Mr. Davenport's "principal letters of thanks from patients are preserved in a large book which he carefully treasures. Among these are communications from and on behalf of such illustrious personages as Her Majesty the Queen, the Prince and Princess of Wales, the Empress Frederick of Germany, the Queen Regent of Holland, the Queen of Denmark, Prince and Princess Christian." Evidently Mr. Davenport has made to these royalties communications of some sort, to which unfortunate secretaries have given the usual formal replies, and Mr. Davenport now tries to humbug the public through the medium of the *Portsmouth Times* into believing that Her Majesty the Queen and the others have as patients sent him "letters of thanks." Having read so much of the article, we instinctively looked lower in the column to find the religious tag which such persons as Mr. Davenport very usually add to their manifestoes. And we found it, the representative of the *Portsmouth Times* having duly reported it. Mr. Davenport, we are informed, "claims that the power to cure various diseases is with him a gift—'A gift from God.' He was induced to go out curing the sick as he is now doing by hearing a sermon preached on the Parable of the Talents some years ago." Faugh!

T. J. W. should consult a solicitor on the actual wording of the agreement. We are not aware of any custom in the matter, but if a radius is to be dealt with it surely must be calculated as the crow flies from the nearest point of the respective premises.

WANTED A SURGICAL PHIDIAS!

To the Editors of THE LANCET.

SIRS,—I would be deeply indebted to you were you to give me the benefit of your advice on the following. I am particularly dissatisfied with my personal appearance and am seriously considering whether it would not be feasible to have some operation performed with regard to three points. Firstly, my nose at the tip is thick and round, instead of being constructed of planes; now, were the nostrils slit vertically at the end and joined closer together and a horizontal section taken out a great deal of the awkwardness would disappear; also, though young, my nose has in parts distended blood-vessels, giving a red appearance whenever I feel cold; now, would it not be practicable to cover it with skin from the arm or elsewhere? Secondly, my lips are unfortunately thick and clumsy; would it not be possible to take off a layer from the inside, even at the expense of their becoming rather shapeless? Lastly, my chin is very receding and rather dragged to one side; could not the introduction be effected of some extraneous living bone, say of the leg of a dog? A triangular piece of bone placed at each angle of the jaw would increase the length and breadth of the jaw, supposing sufficient room for operation could be procured by slitting the skin under the chin and pushing it up; the muscular tissue at the bottom of the tongue might be slit at intervals to allow it to adapt itself to the necessarily increased area. The bone might be held in place, till it grew together, by being wired, and a silver horse-shoe plate placed on the inside of the curve would be absorbed in the system eventually. What would be the probability of gangrene or similar disease? I will be deeply grateful if you will give me your genuine opinion on the above, and tell me of some one whom I might consult on such fantastic surgery when I come up to town in two or three weeks, and suggest the possible cost, as in addition to these disadvantages my complexion has always been an ugly, ashy-grey, sallow colour, such as I have never seen anywhere. I am quite ready to run a fair amount of risk to have these, as far as possible, obviated. Thanking you beforehand.

I am, Sirs, yours truly,

May 4th, 1896. SWALLOW.

*** We make an exception to our usual rule of not publishing letters from patients in favour of our correspondent, who seeks the aid of what he truly denominates "fantastic surgery," because his letter appeals to our sense of humour.—ED. L.

DUTIES OF MEDICAL OFFICERS OF HEALTH.

J. A. R.—There is no book on the subject so far as we know; but in vol. ii. of "A Treatise on Hygiene and Public Health," edited by Stevenson and Murphy, and published by Messrs. J. and A. Churchill, our correspondent will find an article by Dr. Alfred Ashby giving the information he requires. "Difficulties under the Notification Act," published at the office of THE LANCET, price 6*d.*, will also be found useful.

Clerk.—It is impossible to decide positively either for or against a miscarriage having occurred at two months if no product of conception, recognisable either by the naked eye or the microscope, can be found. As regards probability, if the patient was perfectly regular before and then missed two months pregnancy would naturally be thought of. On the other hand, a woman aged forty-four years may easily miss two months and then have a severe hæmorrhage with clots, some of which may temporarily lodge in the uterus owing to the approach of the menopause.

Mr. F. J. Boehm.—We are unable to review the work mentioned, but any preparations sent for analytical report will receive attention.

W. N. H.—We never recommend individual practitioners. Our correspondent must consult his own medical man.

TRAINING OF A MALE NURSE.

To the Editors of THE LANCET.

SIRS,—Could you or any of your readers oblige me by informing me of any hospital where a suitable lad could be trained as a sick attendant? I am, Sirs, yours faithfully,

A. W. LEMARCHAND, L.R.C.P. Lond., M.R.C.S. Eng.

Barnstaple, May 5th, 1897.

Mr. Pugin Thornton's surmise is quite incorrect. We have tested the salt carefully, with absolutely negative results as to the presence of iodine.

NECROPSY, AUTOPSY, OR NECROTOMY.

A WRITER in the *Journal of the American Medical Association* is of opinion that the words "autopsy" and "necropsy" do not sufficiently define a post-mortem examination, for he says that the former simply means "seeing for one's self," and the latter need not imply more than a superficial inspection. He therefore suggests the word "necrotomy" as being preferable.

M.B., C.M.—The medical gentleman's name does not appear in the current 1897 Register. He died in 1896.

Mr. Brindley James.—One of the books has already been reviewed in our columns and the other has not been submitted to us.

H. W. T. (Bath).—We never recommend individual practitioners. Our correspondent must consult his own medical man.

Leeds Student should consult a medical man.

ERRATA.—In the pass-list of the University of Edinburgh which appeared in THE LANCET of May 1st, the name in the list of those passing the Second Professional Examination (old regulations) printed as "E. B. Anderson" should have been *E. B. Anderton.*—In the report of the Hunterian Society supplied to us, and published in our issue of April 24th, the remarks attributed to Dr. Butler Harris gave a false impression. Dr. Harris really said that ozone used in an inhalation of more than 10 per cent. strength would be too irritating in pneumonia, but might be useful in phthisis and bronchiectasis.

During the week marked copies of the following newspapers have been received:—*Todmorden News, Huddersfield Chronicle, Chatham News, Cambs Times, Banffshire Advertiser, Durham Advertiser, North Devon Herald, Cheltenham Examiner, Newcastle Journal, Loughborough Monitor, Wolverhampton Chronicle, Times of India, Pioneer Mail, Worcestershire Advertiser, Boston Herald, Yorkshire Post, Dudley Herald, Herts Reporter, Rochester Journal, Leicester Post, Bristol Mercury, Scotsman, Ripley News, Lowestoft Standard, Maryport News, South-Eastern Gazette, Builder, Liverpool Daily Post, Tonbridge Telegraph, Bournemouth Directory, Kendal Mercury, Leeds Mercury, Newport Advertiser, Birmingham Gazette, Architect, Manchester Courier, Salisbury Times, Ilfracombe Gazette, Sheffield Telegraph, Bradford Observer, East Anglian Daily Times, Isle of Wight Observer, Hampshire Post, Royal Cornwall Gazette, Brighton Gazette, Richmond and Twickenham Times, Radnor County Times, Reading Mercury, Local Government Chronicle, City Press, Hertfordshire Mercury, Mining Journal, Weekly Free Press and Aberdeen Herald, Sanitary Record, Weekly Times and Echo, Glasgow Evening News, Public Health, Surrey Advertiser, General Advertiser (Dublin), Glasgow Herald, Local Government Journal, Derbyshire Times, Australasian Medical Gazette, Taunton Echo, Drogheda Advertiser, Kidderminster Shuttle, Kidderminster Sun, The World, Le Gaulois (Paris), Kelso Mail, Echo, West Middlesex Herald, Ossett Observer, Mirfield Herald, Keble's Margate and Ramsgate Gazette, &c., &c.*

THE APPLICATION OF MODERN METHODS TO HYPODERMIC MEDICATION.

THE initiation of the hypodermic system of medicine occurred early in the present century; but much appreciated as it was from the moment of its introduction, its development was for long impeded by the unreliability of the readily deteriorating stock solutions of necessity generally used in the early days. It is not until towards the close of the century that the introduction of Hypodermic "Tabloids" brought with it possibilities hitherto unhoped for.

The medical practitioner can now carry about with him at all times a few tubes which will make a complete hypodermic armamentarium. The dosage is absolutely accurate, the active principle absolutely pure, and the substance with which the alkaloid or other active principle is combined is quite stable and innocuous.

The BRITISH MEDICAL JOURNAL reports on Hypodermic "Tabloids" that they are "free from irritative salts," thus recognising this very important characteristic; and THE LANCET also says of them that they are "very soluble and not at all irritating." Further "Tabloids" obviate the possibility of over-dosage, since each contains one dose and no more.

ABRIDGED LIST OF HYPODERMIC "TABLOIDS."

Aconitine Nitrate	1-260 gr.
Apomorphine Hydrochlorate	1-15 & 1-10 gr.
Atropine Sulphate	1-160, 1-100, & 1-60 gr.
*Caffeine Sodio-salicylate	1-2 gr.
Cocaine Compound (Strong, Medium, and Weak Anæsthetic).	
Cocaine Hydrochlorate	1-10, 1-6, *1-4, & *1-2 gr.
Codeine Phosphate	1-4 gr.
*Cornutine Hydrochloride	1-60 gr.
Curare	1-12 gr.
Digitalin	1-100 gr.
Ergotinine Citrate	1-200 & 1-100 gr.
Ergotinine Citrate	1-100 gr.
Strychnine Sulphate	1-20 gr.
Eserine Salicylate	1-100 gr.
†*Eucaine Hydrochloride	1-3 & 1 gr.
Homatropine Hydrochlorate	1-250 gr.
Hyoscine Hydrobromate	1-200 & *1-75 gr.
*Hyoscyamine Sulphate	1-80 & 1-20 gr.
Mercuric Chloride	1-60 & 1-30 gr.
Mercury-Sozoiodol	1-4 gr.
Morphine Bimeconate	1-8, 1-6, 1-4, & 1-3 gr.
Morphine Hydrochlorate	1-6 & 1-4 gr.
Morphine Hydrochlorate / Atropine Sulphate	1-6 gr. / 1-70 gr.
Morphine Sulphate	1-12, 1-8, 1-6, 1-4, 1-3, *1-2 & *1 gr.
Morphine Sulphate with Atropine Sulphate, 1-12 & 1-250; 1-8 & 1-200; 1-6 & 1-180; 1-4 & 1-150; 1-3 & 1-120; *1-2 & 1-100 gr.	
Nitroglycerin (Trinitrin)	1-250 gr.
Picrotoxin	1-60 gr.
†Pilocarpine	1-10, 1-6, *1-3 & *1-2 gr.
Potassium Permanganate	2 gr.
*Quinine Bihydrochlorate	1 & 3 gr.
*Quinine Hydrobromate	1-2 gr.
Quinine Hydrochloro-Sulphate	2 gr.
*Sclerotic Acid	1-2 & 1 gr.
*Sparteine Sulphate	1-2 gr.
Strophanthin	1-500 gr.
Strychnine Nitrate	1-15 & 1-10 gr.
Strychnine Sulphate	1-150, 1-100, & 1-60 & 1-30 gr.
*Stypticin (Cotarnine Hydrochloride)	1-4 gr.

Supplied in tubes of non-actinic glass, each containing 20 "Tabloids" except those marked with an asterisk, which contain only 12, at 6d. and 8d. per tube.

† *Prices on request.*

'Saxin'

(Trade Mark.)

Is a delicious sweetening agent, about 600 times sweeter than sugar, and has been aptly termed 'the sweetest thing on earth.' 'Saxin' is indicated in diabetes, gout, glycosuria, obesity, etc., because it undergoes no change in the system. A 1/4 gr. 'tabloid' of 'Saxin' is equivalent to one lump of best loaf sugar. A small bottle containing 100 or 200 can be easily carried in the vest pocket.

Supplied at 7d. and 1s. 1d. per bottle.

BURROUGHS, WELLCOME & CO., LONDON and SYDNEY.

'Emol-Keleet'

A natural powder containing a large proportion of native silicates, employed as a diluent for such potent therapeutic agents as Loretin, Iodoform, Dermatol, Boric Acid, etc., and as a drying and dusting powder.

Its soft, silky texture, soothing influence, and other valuable qualities enhance its healing action. It has proved successful for drying weeping surfaces when all other powders have failed.

Supplied in tins at 9d. each.

BURROUGHS, WELLCOME & CO., LONDON and SYDNEY.

"APENTA"

IN THE TREATMENT OF **OBESITY,** AND ITS INFLUENCE ON CHANGE OF TISSUE.

Observations in **Professor Gerhardt's** *Clinic in the Charité Hospital, Berlin.*

THE *Berliner Klinische Wochenschrift* of March 22nd, 1897, publishes a Report upon some experiments that have been made under the direction of **Professor Gerhardt,** in his clinic in the Charité Hospital at Berlin, demonstrating the value of **Apenta** Water in the **treatment of obesity** and **its influence on change of tissue.**

"Such experiments," it is observed, "could not be carried out until quite recently on account of the inconstant composition of the bitter waters coming into the market. In this respect the **Apenta** Water is favourably circumstanced," and **it was chosen for these observations because of its constancy of composition.**

The conclusion arrived at as to the value of **Apenta** in the treatment of obesity, and as to its influence on tissue-change, was that **it "succeeded in producing a reduction of fat in the body without detriment to the existing albumen,"** and that **"the general health of the patient suffered in no wise, and the cure ran its course in a satisfactory manner."**

A Clinical Lecture
ON
THE BALL-VALVE GALL-STONE IN THE COMMON DUCT.

Delivered at the Johns Hopkins Hospital on Jan. 22nd, 1897,

BY WILLIAM OSLER, M.D., F.R.C.P.,
PROFESSOR OF MEDICINE AT THE JOHNS HOPKINS UNIVERSITY.

GENTLEMEN,—I will begin this lecture by showing you two interesting specimens. The first consists of the stomach, duodenum, and liver. Even from a distance you can see a nodular projection beneath the mucosa of the duodenum. On closer inspection this is seen to correspond to the papilla biliaria, the orifice of which lies a little to the side of the most prominent part of the projection. This nodular body is a hard, firm mass which can be moved up and down, and as I make it appear at the orifice of the duct you see that it is a rounded, dark gall-stone much too large to escape. On moving it up and down it cannot be passed out of the duodenal portion of the duct, but in this it has considerable play. On examining from the side of the duct the stone is seen to lie in a greatly distended diverticulum of Vater. The common duct is of about the size of my index finger, and the main hepatic ducts are also dilated. The cystic duct is wide, and the gall-bladder is perhaps a little enlarged. It did not at the time of the necropsy contain any stones. The dilated bile-ducts and the gall-bladder contained bile-stained mucus. There was neither erosion nor ulceration in the bile passages. I have kept this specimen carefully for nearly ten years, and have frequently demonstrated it to classes of students. The history of the case is very instructive, particularly in connexion with the patient whom you will see in a few minutes.

In September, 1887, when I took charge of certain of the medical wards in the Philadelphia Hospital, there was a woman, aged forty years. It was the third or fourth time she had been admitted, each time with chills, fever, and jaundice. The attacks had recurred on and off for two years, during which period she had not passed two months without some tinge of icterus. The case had excited a good deal of attention, and I remember that in 1886 Dr. Bruen brought to me some of her blood to examine for the malarial parasites. The diagnosis of abscess of the liver had been made on several occasions, and the liver had been twice aspirated. When she first came under my care she was up and about in the ward, and showed only the slightest lemon tint of the skin and of the conjunctivæ. The stools were dark coloured. The liver appeared to be a little enlarged; the gall-bladder could not be felt. Early in October she had an attack of violent pain with vomiting and a moderately severe rigor, after which the temperature rose to nearly 104° F., with ephidrosis, the entire paroxysm lasting for more than twelve hours. The following day she was much more jaundiced, the urine was very dark in colour, and the stools were putty-like. The liver was sensitive on pressure; the gall-bladder could not be felt. The jaundice deepened for three or four days and then gradually became less marked. Throughout the winter at intervals of a few weeks she had four or five attacks of a similar character. I lectured upon the case as one of Charcot's hepatic intermittent fever, due probably to a gall-stone lodged in the common duct, to which opinion I was led from the study of cases which I had seen in Montreal. Early in February I asked Dr. White to see the patient, and she consented to an operation. Perihepatitis was found at the margin of the liver, the gall-bladder was not enlarged, and no gall-stones could be felt in the gall-bladder or in the duct. Three days subsequently she died from peritonitis.

Naturally I was much chagrined at the negative result of the operation. A necropsy was refused, and the friends removed the body to the country, but a personal interview enabled me to procure an examination, and I was allowed to remove the organs which you see before you for careful dissection. This patient had had for a period of nearly two and a half years attacks of jaundice with chills and fever—a very characteristic picture of the intermittent hepatic fever which Charcot and others have so fully described.

The second specimen is an almost exact counterpart. Projecting from beneath the mucous membrane of the duodenum close to the papilla biliaria is a nodular body of the size of an almond which can be pushed down to the orifice of the duct, when it is seen to be an oval gall-stone lying in the diverticulum of Vater, in which it has a certain degree of mobility. At the necropsy in this case it was very interesting indeed to note that on firm pressure on the gall-bladder bile could be forced past the stone into the duodenum. Both cystic and the common ducts are dilated to about the size of the little finger. The gall-bladder is of the size of a small pear. There is no other gall-stone. The contents of the common and cystic ducts were thin, yellow bile containing some dark granular matter. The colon was adherent to the gall-bladder and to the under surface of the liver. The liver weighed 1570 grammes; the surface was a little roughened. The cut section was bile-stained and showed moderate dilatation of the smaller ducts. The consistence of the organ was increased. It may be mentioned also in connexion with the case that there was a chronic diffuse nephritis. The further details of the necropsy, which is No. 758 in the Johns Hopkins Hospital Records, do not concern us. The history of this case has not quite the same interest as the other, but it presents identical features.

The patient was a man, aged sixty years, who was admitted to the hospital on Dec. 22nd, 1895. I had seen him on Nov. 23rd previously and had learned that he had been ill for rather more than three months with recurring attacks of slight jaundice and paroxysmal pain in the right side, which were sometimes accompanied by chills and fever. When I saw him he was slightly jaundiced, there was much irritability of the stomach, the liver was not enlarged, and the gall-bladder could not be felt. The condition had varied very much from time to time, being sometimes better and sometimes worse. He had had numerous attacks of chills and fever, following which the jaundice would become more intense. He had been actively treated for malaria. He grew progressively weaker, and when admitted to the hospital on Dec. 22nd he was very feeble and apathetic. He had a sallow, slightly jaundiced colour, with distinctly jaundiced conjunctivæ. The pulse was 106; he had no fever. His temperature at 4 A.M. on the 23rd was normal. He shortly afterwards had a chill, and by noon his temperature had risen to nearly 103° F. He had a great deal of pain in the right side of sufficient severity to require morphia. Ephidrosis followed the fever, and the patient seemed to be somewhat more jaundiced. There was a small amount of albumin in the urine with granular casts and a distinct reaction for bile pigment. He became much more prostrated after this attack, had a good deal of pain at intervals, and was drowsy and apathetic. On the night of the 30th he had a severe attack of general convulsive twitching, and a slight rise in the temperature with ephidrosis occurred on the 31st. On Jan. 2nd he had Cheyne-Stokes respiration, became unconscious, and died on Jan. 4th. In this case the attacks of pain and intermittent paroxysms of fever enabled me to make a very positive diagnosis of a gall-stone in the common duct.

The consideration of these two cases and the inspection of the specimens will enable you to appreciate better the symptoms presented by the case which I will now ask to have brought into the lecture-room. The history of this patient, as taken by Dr. Gwyn, is as follows:—

A married woman, aged twenty-eight years, was admitted to the hospital on Nov. 28th, 1896, complaining of pain in the epigastrium. She had been a very healthy woman and had had two children. In July, 1894, she had a miscarriage. The first attack of her present trouble (in September, 1894) came on with vomiting, headache, and pain in the abdomen. The skin at this time was very sallow, but she did not think she became jaundiced. The urine was of a dark colour. She had distinct chills, severe and shaking. After an illness of three weeks she recovered and remained quite well until June, 1895. In this second attack she had nausea and vomiting, itching of the skin, jaundice, chills and fever, and pain in the epigastrium. It lasted about four weeks. The third attack was in September, 1895. She had, however, no paroxysm of pain, but she had chills at intervals, and there was slight tinging of the whites of the eyes. Recurring attacks of chills and fever persisted until Christmas. The fourth attack came on in March, 1896. It began with nausea, vomiting, and pain in the epigastrium and under the right costal margin

Hosted by Google

passing back to the right shoulder. She became very jaundiced and had much itching of the skin. The pain was much more intense than in any previous attack, and she had to have morphia. She had recurring chills and fever, and the jaundice persisted for nearly three months. The fifth attack, for which the patient came to the hospital, began on Sept. 1st with nausea, occasional vomiting, headache, itching of the skin, deep-coloured urine, and slight tinging of the conjunctivæ. She had no pain in this attack, but frequent chills recurred until a week before admission to the hospital. The jaundice had been very slight. The chills had been the same in all the attacks. They came on every few days, sometimes quite regularly every other day, lasting fifteen or twenty minutes, and were followed by high fever and occasional ephidrosis. On admission the patient was found to be a well-nourished, healthy-looking woman. The skin was a little sallow, not distinctly jaundiced, and the conjunctivæ were slightly tinged. There was nothing abnormal on examination of the chest. The abdomen was a little full, tympanitic, with no areas of abnormal resistance. The liver dulness began at the sixth rib in the nipple line and barely reached the costal margin. The edge of the liver could not be felt. There was no tenderness on deep pressure in the epigastric region. The gall-bladder was not palpable. The spleen could not be felt. On Nov. 30th the yellow colour of the skin was more marked, and there was bile reaction in the urine. The stools were light in colour. On Dec. 4th there was a little tenderness in the right hypochondriac region, and the patient had had slight pain in this region on the previous day. She remained in hospital until Dec. 6th. She had no chills, and the temperature was under 100° F. The jaundice had almost disappeared and she had gained in weight. She felt well until the day before Christmas, when she became nauseated and was sick at her stomach. On Christmas eve she had a violent chill with high fever and pain of such severity in the region of the liver as to require a hypodermic injection of morphia. The jaundice was intensified the following day and increased considerably. She returned to-day (Jan. 22nd, 1897) to report upon her condition. You see that she is a healthy-looking woman, well nourished, and were it not for the very slight jaundice persisting nothing special would be noted about her. The abdomen is full, a little large, and the panniculus is well preserved. Palpation in the liver region is negative. There is no pain on deep pressure. The edge of the liver cannot be felt, and the gall-bladder is not palpable. Within two years and four months this patient has had at least six attacks of pain in the region of the liver, with chills, fever, and jaundice. The latter has been a variable symptom, sometimes very intense, but if we may judge from her condition on admission on Nov. 28th, 1896, even in the intervals the jaundice does not entirely disappear.

You notice the remarkable similarity in the history of these three cases: jaundice, usually of slight grade but increasing at times in intensity, attacks of pain in the region of the liver, and paroxysms of intermittent fever. The duration of the illness in the first case was two years and a half, in the second between four and five months, and in the woman you have just seen two years and four months. I have no hesitation in making the diagnosis of ball-valve stone in the common duct in the case before you, but before I proceed to speak fully of this condition and of its symptomatology, let me refer for a moment to two anatomical points of special interest in connexion with cholelithiasis.

We do not know what starts a stone on its migrations. In a large proportion of all cases so long as the calculi remain in the gall-bladder they do little or no harm. This statement is borne out by the frequency with which gall-stones are found post mortem in persons who have presented no symptoms whatever and whose gall-bladders show little or no change. Once started, a stone has two main obstacles to overcome. The cystic duct is not a simple tubular structure, but has a very remarkable reduplication of its mucosa known as the Heisterian valve. If you attempt to pass a probe or a pair of probe-pointed scissors into the cystic duct you will find that the point is interrupted by valvular folds which sometimes encircle the entire tube and are very much like the valvulæ conniventes. Sometimes the arrangement is that of a spiral valve. In other cases there is no symmetry whatever, and the valves may have the free edges directed upwards towards the gall-bladder, or downwards towards the common duct. Both at the neck of the gall-bladder and at the junction of the cystic with the hepatic duct the folds may be unusually prominent. No possible arrangement could be more unfavourable for the passage of a gall-stone; a small one may get lodged beneath the valvular folds, indeed I have seen one tucked in beneath the strong fold sometimes present at the neck of the gall-bladder. Biliary colic is probably an expression of the difficulties a stone has in passing through the valvular folds in the cystic duct. Once in the common duct a stone of medium size has little or no difficulty until it reaches the duodenal portion, the anatomical relations of which may for a moment engage our attention. The bile and pancreatic ducts open by an orifice which is smaller than the lumen of the conjoint ducts, and the opening is usually on a prominent papilla on the mucosa of the duodenum. Between the point of junction of the two ducts and the orifice in the papilla biliaria there is a dilatation, the diverticulum or ampulla of Vater. In this part of the duct the ball-valve stone often lodges. The intermittent filling of the gall-bladder almost assumes the existence of a sphincter choledochi, yet no mention is made of such a structure in the text-books (Quain or Henle). Oddi[1] has demonstrated this sphincter in different animals and in man, and Dr. L. F. Barker has been kind enough to prepare for me several specimens by his method which show the fibres very clearly. Doyon[2] claims to have determined the biliary reflex—the afferent fibres pass in the vagus, and the efferent in the splanchnic—and states that stimulation of the central end of the vagus causes contraction of the gall-bladder and at the same time relaxation of the sphincter choledochi. Upon the importance of this sphincter choledochi in the history of gall-stones very little stress has been laid, except by Leichtenstern in his recent section on Diseases of the Bile Passages in Penzoldt and Stintzing's "Handbuch."[3] He states that sometimes macroscopically, as well as microscopically, hypertrophy of this sphincter can be seen in old cases of gall-stone impaction. To another point he refers (of great importance in connexion with the condition of the gall-bladder in these cases)—viz, that the physiological filling of the gall-bladder with bile is a function of this sphincter. It is in this duodenal portion that the typical ball-valve stone is most frequently found, as in the two specimens which I have demonstrated to you, though it may lie loose in the duct. Let me call to your remembrance the fact that pressure on the gall-bladder in the second specimen could make the bile flow past the obstructing stone. My attention was first called to this condition many years ago, and in a lecture which I published in 1881,[4] on Some of the Effects of Chronic Impaction of Gall-stones I remarked "that a gall-stone may remain permanently lodged in the pars intestinalis and yet not be impacted. In such instances it may still permit the passage of bile past it, or it may act as a ball valve, only permitting of the flow when the distension behind has reached a certain point." In several cases the stone in the diverticulum of Vater was so placed that it could be moved up and down to act as a sort of ball valve; and clinically I had had an opportunity of studying two cases (Nos. 11 and 12 of those reported in the lecture) in which the remarkable train of symptoms seemed best explained by this ball-valve action of a stone in the common duct. Subsequently, in a paper on Fever of Hepatic Origin,[5] particularly the intermittent pyrexia associated with gall-stones, I called attention especially to the importance of recognising a group of cases of obstruction of the common duct characterised by the following symptoms: "First, jaundice of varying intensity, deepening after each paroxysm, and which may persist for months or even for years; second, ague-like paroxysms characterised by chill, fever, and sweating, after which the jaundice usually becomes more intense; and, third, at the time of the paroxysms pains in the region of the liver, with gastric disturbance." In this paper I considered at length the question of the hepatic intermittent fever which the French physicians, particularly Charcot, had so carefully described, and emphasised the following points: that recovery might follow even, as shown by the cases, after duration of the chills and fever and jaundice for several years; that this condition could be differentiated from suppurative cholangitis; and that the symptoms were probably caused by the ball-valve action of the stone. I added the following statement: "In all of these

cases the obstruction is not complete, as shown by the presence of bile in the stools for long periods at a time. The association of the chills and fever with intensification of the jaundice must be more than accidental. The two must be correlated in some way, in all probability through a transient impaction of the stone in the duct. Such a condition might induce the chill, either through reflex irritation, as held by Murchison, or by preventing the escape from the bile passages of toxic ingredients—ferments produced by the action of micro-organisms—which are absorbed into the blood instead of escaping freely into the bowel. The impaction is probably overcome by a gradual increase in the *vis a tergo* until the duct is stretched to a point which permits the calculus to fall back into a wider portion. The pressure may reach such a grade that the stone is forced out, as happened in Case 2, and very likely in the other cases in which recovery followed." In both editions of my "Text-book of Medicine" I recognised the possibility of diagnosing the presence of the stone in the common duct and of differentiating the catarrhal from the suppurative cholangitis. I had seen many cases which seemed to bear out these statements, and had been in the habit in my classes and at meetings of societies of speaking of the ball-valve action of certain gall-stones. Not having seen my papers, Christian Fenger of Chicago, in the February and March numbers of the *American Journal of the Medical Sciences*, 1896, made the statement that "neither Courvoisier nor any other author seems to have observed the ball-valve action of floating stones in the common duct."

Symptoms.—What are the symptoms of gall-stones in the common duct? They are very variable. There may be none; it may be dilated and full of stones so arranged that the bile can flow past them without much, if any, obstruction. I have twice seen a single small stone in the common duct which had apparently caused no disturbance. No one has laid down more clearly the symptoms of stone in the common duct than Naunyn:[6] "(1) The continuous or occasional presence of bile in the fæces; (2) distinct variations in the intensity of the jaundice; (3) normal size or only slight enlargement of the liver; (4) absence of distension of the gall-bladder; (5) enlargement of the spleen; (6) absence of ascites; (7) presence of febrile disturbance; and (8) duration of the jaundice for more than a year." Now what I wish to bring out in connexion with the case you have just seen is the probable association of the intermittent features—pain, rigors, fever, and jaundice—with the ball-valve action of a stone in the common duct or its diverticulum—a view which offers a reasonable explanation of the remarkable phenomena of the case. This patient when you saw her in the ward looked a well-nourished, healthy woman with only the slightest trace of jaundice, chiefly noticeable in the conjunctivæ. Some of you may remember that I predicted another attack as very probable within a few months. In these protracted intervals I take it the gall-stone lies loose in the duct or its ampulla, and the pressure is sufficient to force the bile past it, though the persistence of the slight jaundice for weeks or months shows that the flow is not quite free. The onset of the paroxysms may be due to an acute infection with swelling of the mucosa about the stone and transient complete blocking of the duct, or the stone may be jammed tightly against the orifice of the duct. Impaction would account for the pain and the jaundice; the intermittent paroxysms of fever are probably due, as I suggested in the extract read a few minutes ago, to the absorption by the blood of the toxins produced by the micro-organisms which in the intervals of impaction pass into the bowel. The impaction is followed, of course, by stasis of the bile, a condition very favourable to the growth of the micro-organisms. I have recently had occasion to discuss with you the question of infection of the bile passages in a case of typhoid fever with colic and jaundice. Various organisms may be present without doing damage. Thus typhoid bacilli were present in the bile passages of seven persons who died from typhoid fever (seven of fourteen examined) not one of whom had during life given any signs of liver trouble. A stone in the common duct with stasis of the bile and catarrhal cholangitis favours the growth of organisms, which are always seeking entrance—in healthy persons in vain—at the portals of the ducts. Unfortunately in the necropsy upon the case from which the second specimen was obtained, though cultures were made from many parts—as is the custom in the post-mortem room—which were sterile, there is no specific note in the report about the bile passages. Infective cholangitis is present in all these cases, and to it the febrile phenomena are due. The large experience which we are daily receiving from the surgeons should very soon give us positive data as to the varieties of micro-organisms associated with this condition. To one point I would here direct your particular attention—viz., that this infective cholangitis may persist for years without causing suppuration in the ducts or ulceration of their walls. A knowledge of this fact has a very direct bearing on the prognosis and diagnosis of these cases.

Diagnosis.—The diagnosis of a stone in the common duct may often be made with reasonable probability, and while the rules laid down by Naunyn could not be bettered I am anxious to go further and to urge the possibility of recognising as a special variety the ball-valve stone. The group of symptoms to which I have referred (and which were shown so graphically in the case of the patient whom you have just seen as well as in those from which the specimens were taken) have not been sufficiently recognised by authors, and when recognised have been too often misinterpreted. Let me again recall them. They are chronic jaundice, rarely deep, varying in intensity, at times almost or entirely disappearing to deepen invariably after a paroxysm (the icterus may be of maximum grade and associated with intolerable itching); pain, often a constant sense of discomfort, sometimes only an obscure gastric distress, and at others agonising, griping, and like ordinary liver colic; fever, occurring in paroxysms, usually preceded by a chill and followed by sweats, but there may be pyrexia alone; the chills may be quotidian or tertian in type or they may recur for weeks in succession on the same day; the spleen usually enlarges during the febrile paroxysms. Though persisting for months or even for years, the general health may be little, if at all, impaired, and in the intervals between the paroxysms a person may be able to work as usual. The cases are usually diagnosed as chronic malaria, abscess of the liver, or suppuration of the bile passages.

The regularity of the chills and the slight jaundice naturally suggest malaria. In almost every one of my cases the diagnosis of malaria had been made and the patient had been dosed with quinine for weeks or months. In Case 7, a man, aged sixty-four years, who had had jaundice with the intermittent fever, &c., for eleven months, was treated by a well-known Carlsbad physician for malaria, which opinion was concurred in by at least half a dozen physicians in Europe and in this country. The mistake is a very natural one, particularly if the patient has not very intense jaundice. The paroxysm is almost identical in its features with that of simple intermittent malarial fever. The periodicity may be striking, the chills recurring like a tertian or a quartan fever. The good condition in the interval, the absence of great enlargement of the liver or of enlargement of the gall-bladder, and the presence of enlarged spleen are all points which strongly suggest malarial fever. On the other hand, the absence of plasmodia in the blood, the occurrence of pain at the onset of the paroxysm, and the deepening of the jaundice, which is usually of a grade more intense and quite different from the slight sub-icteroid hue of chronic malaria, should be sufficient to differentiate a case. Cases of simple intermittent fever do not resist the action of quinine. Chronic paludism also as a rule is associated with much more pronounced enlargement of the spleen.

Abscess of the liver can usually be excluded by the absence of tenderness and enlargement, local or general, the variable character of the jaundice, the good condition of the patient in the intervals of the paroxysms, the very chronic course in many cases, and the absence of progressive deterioration of health and strength. In the case from which the first specimen was taken the diagnosis of abscess of the liver had been made by several physicians, and exploratory punctures had been made on two or three occasions. Her general condition at the end of two years' illness seemed to me to exclude abscess.

As regards suppurative cholangitis, infective processes in the bile passages are very prone to end in pus formation, an only too common sequence of chronic impaction of stone in the common duct. I show you here a coloured drawing of a case of this sort in which you see the stone in the ampulla of Vater; the ducts were enormously dilated, even to the surface of the liver; the gall-bladder was greatly enlarged, full of pus, and the walls ulcerated. Now a majority of writers have

[6] Klinik der Cholelithiasis, and New Sydenham Society's edition, 1896, p. 107.

Hosted by Google

regarded the hepatic intermittent fever as an indication, not simply of infective, but of suppurative cholangitis. In the present case, though the condition has persisted for more than two years, purulent inflammation of the bile-ducts can be positively excluded. When this serious complication is present the symptoms are those of pyæmia of a severe grade. Among the points to be considered are the following: (1) increased tenderness in the hepatic region with possibly enlargement of the gall-bladder, as this is a more common event in suppurative cholangitis than in simple obstruction of the duct; (2) the more frequent return of the paroxysms and, in some instances, the irregularly remittent character of the fever; (3) the jaundice is not so intense in suppurative cholangitis, and we do not see the remarkable deepening in colour after the paroxysms; and (4) the general condition of the patient in the intervals is very different in the two conditions. When suppuration exists there are rarely the prolonged periods of apyrexia, the freedom from distress, and the general betterment which are so well illustrated in the case before you. And, lastly, the time element comes in as an important aid in diagnosis. As I mentioned a few moments ago, the good condition when she was in the ward of the patient in the present case was quite inconsistent with the idea of a purulent inflammation in the bile-ducts.

The ball-valve action is more likely to occur with a single stone, but the group of intermittent symptoms are not necessarily present. I have reported a case of a man, aged seventy years, who had been jaundiced for several years, but who had not had, so far as could be gathered, attacks of chills and fever. There was a gall-stone in the diverticulum of Vater which could not be pushed into the common duct. There was not, however, complete obstruction, as on squeezing the duct bile-stained mucus flowed from the orifice. A second stone of the size of an olive lay free in the common duct. I cannot speak positively about the clinical features of this case, which I did not see during life. The common duct may be full of calculi and, as is well known, there may be no suspicion of any trouble during life; the bile may flow, as water does in a rocky stream, between the stones. On the other hand, these cases of multiple calculi in the common duct may present marked intermittency in the symptoms. One of the first cases admitted to this hospital was a man, aged sixty-eight years, who had had jaundice of great intensity of three years duration, during which time he had scarcely passed three weeks without a chill of great severity. He died from cholæmia two days after admission. The common duct was distended into a sac and filled with gall-stones. The gall-bladder was shrunken to a small sac tightly contracted around several gall-stones. There was a small ulceration between the duodenum and the common duct. The walls of the ducts were thickened, not ulcerated, and the contents were a viscid, yellowish, non-purulent material. There was an acute ulcerative endocarditis in this case. Other causes of chronic jaundice do not, so far as I know, give this clinical picture. In the pressure of a new growth, as from the pancreas, the jaundice is deeper, more enduring, as a rule, and there are not these singular intermittent features; pain is not so constant a symptom; infection of the bile passages is less frequent; there are often signs of secondary disease; the gall-bladder is enlarged (Courvoisier's rule) and palpable; there is progressive deterioration of health and strength; and, lastly, there are sometimes the special features of pancreatic diseases—fatty stools, &c.

The presence of the ball-valve stone in the diverticulum of Vater gives a possible clue to the absence of enlargement of the gall-bladder in these cases of obstruction from stone, a point to which a good deal of attention has been paid recently. This interesting observation we owe to Courvoisier, and it is of a good deal of diagnostic significance. Ecklin[7] has recently reviewed the question, and finds that of 172 cases of obstruction of the common duct by calculus in 34 the gall-bladder was normal, in 110 it was contracted, and in 28 it was dilated. Of 139 cases of occlusion of the common duct from other causes the gall-bladder was normal in 9, shrunken in 9, and dilated in 121. It seems quite possible that this absence of dilatation in obstruction by stone is associated with the disturbance in the normal reflex of the sphincter choledochi, an important function of which is, as Leichtenstern states, filling of the gall-bladder.

[7] Annales Suisses des Sciences Médicales, Series iv., Part 3.

Prognosis.—What is the outlook in these cases? Let me give you briefly my personal experience.

CASE 1.—This was that of a woman, aged thirty years, in whom for eight months there were recurring attacks of pain with ague-like paroxysms and intensification of the jaundice. The gall-stone passed and the patient recovered.

CASE 2.—A woman, aged fifty-five years, from July, 1879, until August, 1882, had jaundice of varying intensity with recurring attacks of pain and intermittent fever. This case was one of unusual severity. Recovery was complete. The patient was in good health in 1888 when last heard from.

CASE 3.—A woman, aged forty years, had variable jaundice of two and a half years' duration; there were recurring attacks of intermittent fever with pain; an operation was performed, death ensued, and post-mortem a ball-valve stone was found in the diverticulum of Vater.

CASE 4.—A man, aged seventy years, had had jaundice of varying intensity for eleven months; there were repeated paroxysms of pain and intermittent fever; death followed from cholæmia.

CASE 5.—A woman, aged forty-six years, had been under observation for three years with attacks of pain and intermittent fever with intensification of the jaundice. The patient has been lost sight of.

CASE 6.—A woman, aged twenty-three years, suffered from jaundice of ten months' duration varying in intensity; there were paroxysms of hepatic intermittent fever, but the patient recovered.[8]

CASE 7.—This was that of a man, aged sixty-four years, who had had jaundice for two and a half years (May, 1890, to November, 1892), with recurring chills and fever with intensification of the jaundice; there was very little pain but great loss of weight. The patient has been in perfect health up to date (January, 1897) since recovery.

CASE 8.—A man, aged forty-four years, suffered from intermittent jaundice of many years' (fifteen?) duration; there were innumerable attacks of chills and fever recurring at intervals of from six weeks to six months. Several attacks occurred while under observation in 1892. The patient recovered and has been in perfect health since the spring of 1892.

CASE 9.—A man, aged sixty years, had jaundice varying in intensity for nearly six months; there were recurring attacks of pain with chills and fever; death occurred from cholæmia.

CASE 10.—A woman, aged twenty-eight years, for two and a half years has had intermittent attacks of jaundice with chills and fever. Her general health has been well maintained. This patient is the one now under observation.

Recovery followed spontaneously in five cases (in one after an indefinite period of years, in one after three years, in one after two and a half years, and in two cases after eight and ten months respectively), two died from cholæmia, one case was operated on and died, and one was lost sight of. The dangers are suppurative cholangitis, perforation of the duct, diffuse hepatitis, and remotely the development of cancer.

What shall we advise in the present case? The patient's life has been miserable for more than two years; all sorts of measures have been employed and the Pharmacopœia has been exhausted. The two remedies which are in vogue at present—phosphate of soda in large doses and olive oil—have been tried in vain. The medicinal treatment of gall-stones is a chapter in our therapeutics the leaves of which are best turned very rapidly. The man who believes he can dissolve gall-stones will probably tell you that he can abort an attack of pneumonia and that he can cure locomotor ataxia. So soon as they give serious trouble their removal by operation is the only rational method of treatment. When they are in the gall-bladder the operation in skilled hands has a minimum of risk. Kehr's recent statistics give one hundred and seven cholecystotomies with only one death. The question is a very different one in the common duct cases. The operation is much more severe, the risks infinitely greater, and the results, even in the best hands, not nearly so good. Kehr has, however, had thirty cases with only two deaths—a remarkable record. In the present case the attacks are recurring with greater intensity and greater frequency, the bile passages have stood the irritation long enough, and I have urged her strongly to submit to an operation at an early date.

A knowledge of the significance of the group of symptoms

[8] These cases have been reported in full in an article on Hepatic Intermittent Fever, Johns Hopkins Hospital Reports, vol. ii.

to which I have called your attention will suggest to surgeons the advisability of seeking the obstruction in the terminal portion of the duct. In the specimens before you the stones lie in reality within the duodenum, projecting beneath its mucosa, and would be more accessible through an incision in the gut than by a choledochotomy.

EIGHTEEN CONSECUTIVE CASES OF INTRA-ABDOMINAL HYSTERECTOMY FOR FIBROIDS.

BY WILLIAM DUNCAN, M.D., F.R.C.S. ENG.,

OBSTETRIC PHYSICIAN TO THE MIDDLESEX HOSPITAL; SENIOR PHYSICIAN TO THE CHELSEA HOSPITAL FOR WOMEN; EXAMINER IN OBSTETRICS AND GYNÆCOLOGY AT THE CONJOINT BOARD FOR ENGLAND AND AT THE VICTORIA UNIVERSITY.

THE accompanying table comprises every case (up to the date of writing this article) of intra-abdominal hysterectomy that I have performed. Prior to May 1st, 1896, the extra-abdominal method by means of a clamp (which method some operators still advocate) was that which I always used, with a more or less high mortality; but the advantages of the intra-abdominal method are so great that it seems to me they should be widely known. The steps of the operation being nearly the same in all the cases, it will be sufficient for my purpose if I describe in detail one case only, give a short tabular summary of the rest, and finally make some remarks on hysterectomy.

A woman, aged thirty-eight years, was sent to me by a medical friend. The catamenia, which began at the age of fourteen years, were perfectly regular, and lasted five days without clots or pain. The last period ended on June 15th, 1896. She married on July 4th, 1896, and continued well without morning sickness until Aug. 3rd, when she could not pass her urine, so my friend was called in. He drew off a large quantity of urine by catheter, and then found she had an abdominal tumour reaching above the umbilicus and also filling the pelvic cavity, so he advised the patient's husband to bring her up to me. I saw her on Aug. 12th. She was a thin, healthy-looking woman. The breasts were somewhat tense with blue veins coursing over them, and the areolæ were rather large and dark; no secretion could be squeezed out. On examining the abdomen a large, hard, irregular, and bossy mass could be felt, reaching two inches above the umbilicus. It was somewhat mobile, dull on percussion, but both flanks were resonant. No uterine souffle could be heard over it. On introducing the finger within the vagina it at once impinged on a hard, smooth mass, which filled up Douglas's fossa, pushed down the posterior vaginal wall to near the vaginal orifice, and displaced the os uteri upwards and forwards to such an extent that it was with great difficulty the cervix could be reached at all. Movement of the abdominal tumour bimanually caused movement of that in the pelvic cavity. The case was clearly one of multiple fibroids, and, considering that the patient had "seen nothing" for three weeks before her marriage (which took place thirty-nine days before I examined her), together with the condition of her breasts, I concluded that she had become pregnant immediately after marriage, although coitus was difficult and it was impossible for the penis to reach within some inches of the os uteri. As the patient had felt perfectly well up to the date of her marriage and the fibroids had caused no inconvenience, I advised that, under an anæsthetic, an endeavour should be made to reach and dilate the cervix and empty the uterine cavity of its contents; then it would be seen whether the pelvic mass (which doubtless had increased under the stimulus of pregnancy) would subsequently diminish in size and cause no further pressure trouble and thus obviate the necessity for hysterectomy, to which both the patient and her husband were greatly averse. On the 14th, the patient being anæsthetised and in the lithotomy position, I was able after some trouble to seize the cervix with a volsellum forceps and to just bring the os uteri into view. The cervical canal was next dilated up to No. 14 Hegar, and an early embryo with its decidua curetted away; the uterine cavity was washed out with a 1 in 2000 perchloride of mercury solution, and an iodoform pencil was introduced. After the curettage there was no loss of any kind, and the patient went home on Sept. 1st, the pelvic tumour being *in statu quo*. On Oct. 3rd her condition was practically the same; the patient was very anxious to have the tumours removed, but I advised waiting another month. Between this visit and the following one the patient again had retention of urine. On examination on the 24th I found the mass in the pelvis distinctly larger, so it was agreed to perform hysterectomy without delay. On the 27th, gas and ether having been administered by Mr. George Rowell, I proceeded (with the kind help of Mr. W. H. Battle) to operate. An incision was made extending from the umbilicus to the symphysis pubis, and an opening was made in the parietal peritoneum of this extent. Next the broad ligament on each side was transfixed by means of a long pedicle needle armed with a double silk ligature and passed as near the pelvic wall as possible. One of the ligatures was now tied well outside the ovary and tube, and the ends were cut short. The ends of the other ligature were seized, one in each hand, and by a sawing movement towards the uterus the broad ligament was torn to the extent of an inch or more, and then the ligature was tied. Next, the broad ligament was cut between the two ligatures, leaving the ovary and tube attached to the uterus. After this had been done on both sides the ovarian vessels were, of course, secured, and the uterus was freed; but, owing to the mass in the pelvis, it could not be lifted out of the abdominal cavity. Next, an incision was made (through the peritoneal coat only) across the front and back of the uterus; its upper limit was about two inches above the attachment of the bladder, and laterally the incisions met where the broad ligament was cut. These anterior and posterior flaps were now stripped down until the uterine arteries on each side were exposed. A semicircular needle armed with rather fine silk was now passed well under the vessels on the left side and the ligature securely tied; the same was done to the vessels on the right side. By pulling the tumour well forward the posterior flap was now completely stripped off the growth, which gradually rose out of the pelvis. Then the tumour was cut across just above the level at which the uterine arteries were tied, and removed. There was no bleeding from the stump, out of which a V-shaped piece was now cut. Next the flaps of the stump were carefully brought together by a continuous silk suture, and lastly the two flaps of peritoneum were united over the stump by a continuous silk Lembert suture, beginning at the stump of the broad ligament on one side and ending at the stump on the other side, so that when completed nothing whatever was to be seen in the pelvis except a crescent-shaped line of suture (with the concavity backward) uniting peritoneum to peritoneum. After carefully sponging the pelvic cavity of any blood, the sponges which up to now held the intestines in the upper part of the abdomen were removed, the omentum was drawn down so as to lie against the line of suture, and, lastly, the abdominal incision was sutured in three layers—viz. (*a*), the peritoneal edges with a continuous catgut suture; (*b*) the sheaths of the recti with interrupted fine silkworm gut; and (*c*) the superficial structures in a similar manner to the last. The wound was dressed with iodoform gauze and blue wool, with a flannel bandage over all. The operation lasted one hour and ten minutes. The further progress of the case resembled precisely that of a simple ovariotomy. There was no sickness, the temperature never reached 99·5° F., or the pulse 100. Urine was passed naturally after the third day, the bowels were relieved by an enema on the seventh, the dressings were removed on the same day, and the superficial stitches then removed, the wound having united perfectly. The patient was allowed out of bed in the third week, and went home well in the fourth. On March 19th, 1897, she continued to be in robust health.

Remarks.—It must be admitted by every unprejudiced person who reads the foregoing that the operation as described is incomparably superior both to the extra-abdominal method and also to total removal of the uterus (pan-hysterectomy), for although one of the patients died on the eighteenth day from embolism, this was an unfortunate accident, which could not on post-mortem examination be found to have any direct connexion with the operation; and the whole series of cases might be classed as "successful." It would have been absolutely impossible to remove the tumour by the extra-abdominal method in Cases 5 (described in detail), 13, or 15. Moreover, by the extra-abdominal

Hosted by Google

method there is more danger of hæmorrhage from the stump, death has occurred from dragging of the stump causing intestinal obstruction, recovery is always prolonged, and until the clamp has safely come away after sloughing of the stump the operator never feels happy; whereas after the method I have described there are none of these disadvantages. Lastly, the extra-abdominal method leaves a weak place in the abdominal wall which in not a few cases later gives rise to hernia. It requires no prophet to foretell that in a few years the method of removing uterine fibroids by bringing the fleshy stump outside the abdominal wall and there clamping it will lapse into oblivion as completely as the use of a clamp has done in the performance of ovariotomy. With regard to total removal of the uterus through the abdomen (so-called pan-hysterectomy), I am not in a position to speak so dogmatically, as I have only performed it in one case. I fail, however, to see that total removal (either per abdomen or per vaginam) can have a single advantage over the intra-abdominal method, whereas there are the great disadvantages of laying open the vagina and also having to leave the ligatures on the uterine vessels hanging into the vagina until they come away by sloughing after two or three weeks.

I turn now to the details of the intra-abdominal method: 1. It is well to begin by at once making the external opening sufficiently large to permit the tumour being brought out without the necessity of enlarging the incision later. 2. If the tumour can be brought outside before tying and dividing the broad ligaments, it is best to do so. 3. The flaps of peritoneum should be cut large, so that after removal of the tumour they can be doubled in over the stump (after Lembert's method). In some cases they strip down easily; in others they are rather firmly adherent and require care so as not to be torn or button-holed. I generally use a raspatory for this purpose. 4. The uterine vessels are now exposed on each side and the arteries can be seen and felt pulsating; they are ligatured in the manner already mentioned and, of course, inside the flaps of peritoneum. 5. The tumour, having been rapidly cut across about an inch above the ligatures on the uterine vessels, is removed, when only a slight oozing from the stump will be seen—from small anastomotic vessels probably. If there be

EIGHTEEN CONSECUTIVE INTRA-ABDOMINAL HYSTERECTOMIES.

No.	Age.	Date of operation.	Where performed.	Nature of tumour.	Indication for operation.	Result.	Remarks.
		1896					
1	34	May 1st	Chelsea Hospital	Multiple myomata reaching up to umbilicus	Profuse metrorrhagia	Cured	Ether; bronchitis after operation, otherwise recovery was uninterrupted.
2	40	June 23rd	Private	Multiple myomata reaching above umbilicus	Increasing growth; no hæmorrhage	Ditto	Recovery uninterrupted.
3	44	Oct. 22nd	Middlesex Hospital	Ditto	Profuse metrorrhagia with increasing growth	Ditto	Ditto.
4	40	Oct. 23rd	Chelsea Hospital	Single soft myoma, size of pine-apple	Increasing rather rapidly; no hæmorrhage	Ditto	Ditto.
5	38	Oct. 27th	Private	Multiple myomata filling pelvis and reaching above umbilicus	Retention of urine; no hæmorrhage	Ditto	Ditto.
6	39	Dec. 31st	Middlesex Hospital	Multiple myomata up to umbilicus	Progressive growth; no hæmorrhage	Ditto	Ditto.
		1897.					
7	41	Jan. 8th	Chelsea Hospital	Ditto	Profuse metrorrhagia	Ditto	Ditto.
8	34	Jan. 22nd	Middlesex Hospital	Cystic myoma; size of fœtal head	Ditto	Ditto	Ditto.
9	40	Feb. 12th	Middlesex Hospital	Multiple myomata reaching nearly up to umbilicus	Ditto	Ditto	Ditto.
10	39	Feb. 19th	Chelsea Hospital	Ditto	Ditto	Ditto	Ditto.
11	48	March 12th	Chelsea Hospital	Multiple myomata reaching up to umbilicus	Increasing in size for the last year, causing numbness in left leg and difficult defecation	Ditto	Ditto.
12	49	March 15th	Middlesex Hospital	Multiple myomata filling abdomen reaching nearly to xiphoid cartilage	Increasing growth and metrorrhagia	Died	Pulmonary embolism on eighteenth day.*
13	44	March 18th	Middlesex Hospital	Multiple myomata reaching up to umbilicus, expanding the whole cervix and filling Douglas's pouch	Pressure symptoms; frequent retention of urine	Cured	Recovery uninterrupted.
14	37	March 19th	Chelsea Hospital	Multiple myomata size of small fœtal head	Profuse metrorrhagia and retention of urine	Ditto	Ditto.
15	50	March 19th	Chelsea Hospital	Multiple myomata filling abdomen below umbilicus, filling the right broad ligament and expanding cervix	Progressive growth and metrorrhagia	Ditto	Secondary hæmorrhage on fourteenth day.†
16	40	March 22nd	Private	Single myoma reaching one inch above umbilicus	Metrorrhagia	Ditto	Recovery uninterrupted.
17	35	April 1st	Middlesex Hospital	Multiple myomata extending nearly up to umbilicus	Metrorrhagia	Ditto	Ditto.‡
18	40	April 1st	Middlesex Hospital	Myoma filling pelvis and expanding both broad ligaments	Retention of urine	Ditto	Ditto.

* This patient (Case 12) had not a single bad symptom for eighteen days after the operation, the temperature continued normal the whole time, and she was considered convalescent. On the eighteenth day she ate a hearty dinner; an hour later, whilst using the bedpan, she suddenly fell back and died in a few moments. The post-mortem examination showed death to be due to a large pulmonary embolus which had its origin in the internal iliac vein on the left side. The uterine stump appeared perfectly healthy and the peritoneal flaps over it had become firmly united There was not a trace of any peritonitis.

† This patient (Case 15) was a very pale, unhealthy-looking woman. On the fourteenth day after operation she had a rather profuse hæmorrhage from the vagina, and a tumour formed in the left side of the abdomen reaching up to the umbilicus. The woman was somewhat collapsed. She was put under ether. I then transfused her with four pints of saline fluid, after which I opened the abdomen, cleared out the blood and clots from between the layers of the left broad ligament, put three large and long forceps on some bleeding vessels deep down by the side of the uterine stump, packed round the forceps and the cavity left after the blood was removed with iodoform gauze, and closed the abdominal incision. The gauze was removed and the forceps were taken off after forty-eight hours, and an india-rubber drainage-tube was inserted. An uninterrupted recovery followed.

‡ This case (No. 17) was an unusually difficult one as the myoma was complicated by a suppurating cyst, the size of a fist, between the layers of each broad ligament; both cysts ruptured during removal and the pus escaped into the pelvis. The posterior layers of the broad ligaments were sutured together in the middle line from below upwards, the broad ligaments thus forming one cavity in which was the uterine stump. The cavity was packed with iodoform gauze and its upper margin carefully united to the parietal peritoneum at the lower end of the abdominal incision, leaving of course an opening through which the gauze passed. The rest of the abdominal opening was then closed in the usual way. The patient convalesced without a single unfavourable symptom and the cavity rapidly filled up from the bottom.

Hosted by Google

free oozing or any vessel be seen spouting, then the uterine vessels have not been properly secured, so a second ligature should be passed more deeply on one or both sides. 6. The next step (and one to which I attach great importance) is to cut out a V-shaped piece of the cervix and then to bring the flaps of the stump accurately and firmly together by means of a continuous deep silk suture, thus not only completely arresting any oozing from the stump, but also effectively shutting off any danger of sepsis from the vagina through the cervical canal, which is enclosed between the flaps. 7. Doubling in the peritoneal flaps (according to Lembert's method in suturing intestine) is important; it can be readily done, provided care be taken to cut the flaps, and especially the posterior one, long. Very often the stumps of the broad ligaments can be turned inside the peritoneal flaps, so that at the completion of sewing up no raw surface of any kind whatever can be seen on looking into the abdominal cavity. 8. The most difficult cases are those in which the tumours burrow into one or both broad ligaments, for in these cases after the growths are shelled out a more or less large cavity, or cavities, is, or are, left, in which blood is liable to collect, with danger to the patient. In Cases 15 and 18 the tumours burrowed between the layers of the broad ligaments, so that after I had removed the mass a cavity (into which an ordinary sized glass tumbler would have fitted) was left. This I treated in the following manner. Having tied all oozing points, I whipped the sides of the cavity together by means of a continuous fine silk suture, commencing at the deepest part and proceeding upwards until the sac was obliterated effectually. Then the peritoneal flaps were brought together in the usual way. 9. In not a single instance was there the slightest necessity for the use of a drainage-tube. 10. It will be noted that in Cases Nos. 8 and 14 the tumours were comparatively small, and many operators would have been content with removal of the uterine appendages in order to stop the hæmorrhage and arrest growth; but I considered that having opened the abdomen I was not materially exposing the patient to more risk by performing hysterectomy as described; whereas, on the other hand, it is well known that in not a few cases removal of the uterine appendages has failed to bring about the desired results just mentioned. It was fortunate that I adopted the more radical treatment in Case 8. This patient was sent in under my care by my colleague Mr. Henry Morris. The uterus being symmetrically enlarged and the hæmorrhage profuse, I thought she might have a fibroid polypus in the uterine cavity, so under an anæsthetic I dilated the cervical canal, and on exploring with my finger I found there was no polypus present, but a fibroid the size of a large orange embedded in the anterior uterine wall and pushing inwards the endometrium. A week later I performed intra-abdominal hysterectomy, and on laying open the tumour after its removal found *in its centre a cyst the size of a Tangerine orange*, so that had I been contented with removing the uterine appendages I have little doubt that the tumour would have continued to grow and thus have necessitated a second operation at some future date. 11. Suturing the abdominal walls in three layers is, I think, of sufficient importance to justify the extra time it takes. Since adopting it I have not had a single case in which the scar has subsequently yielded, giving rise to a ventral hernia. 12. Lastly, it seems to me that in the operation herein described we possess a means by which almost every class of cases of uterine fibroids can be effectively and safely dealt with; not only those which threaten life from excessive hæmorrhage or dangerous pressure upon important organs such as the bladder or the bowels, but also those which give rise to discomfort by reason of their large size and compel those who are the subjects of them to lead more or less the lives of invalids.

Harley-street, W.

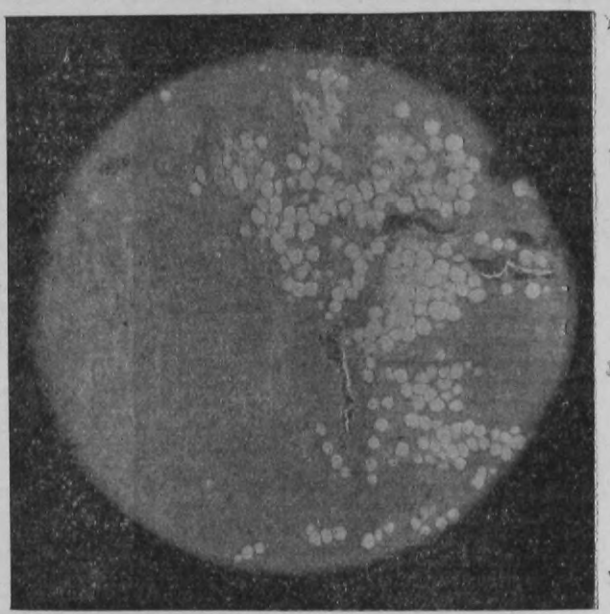
RAILWAY MEN'S CONVALESCENT HOME AT ST. LEONARDS.—On May 4th the Countess of Chichester opened the convalescent home which has just been erected at St. Leonards in connexion with the Railway Mission. The building is of red brick with stone dressing, and is in an excellent situation overlooking the sea. The total outlay has been about £7000, not including the value of the site. The site was purchased for £600 or £700 by Miss Dolby, who was in charge of the old convalescent home at Hastings, and was presented by her to the committee.

ACUTE PANCREATITIS.

BY R. M. SIMON, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM,
With a Pathological Note by
DOUGLAS STANLEY, M.D. EDIN., M.R.C.P. LOND.,
LATE PATHOLOGIST TO THE HOSPITAL.

IT is possible that the subject of this paper is as great a novelty to many as it was to myself until I was brought into contact with a case in March, 1896. The most recent text-books do not refer to it, and there have been from time to time references to isolated cases in British journals, but prior to 1889, when Dr. Fitz published the Middleton Goldsmith lecture in the *New York Medical Record*, there has been no attempt to collate cases or to systematise knowledge. It is to Dr. Fitz, therefore, that recent writers make reference, and to him that all credit for substantiating the existence of the disease should be given. It is possible, or even probable, that his classifications and conclusions need not be accepted in their entirety, but nevertheless his lecture will always remain as a classic and furnish the basis for further investigation. It would be well before discussing the pathology of the disease to give an account of the case which drew my attention to the subject.

CASE 1.—About midday on March 25th I was asked to see a man suffering from persistent vomiting of three days' duration. He had suddenly been seized with a most intense pain a little to the right of the middle line in the epigastrium. The pain quite disabled him and he had to give up his work, that of a night watchman, immediately, and take to his bed. He began to vomit and continued to do so almost without cessation until the time I saw him. I found him lying in bed with a bucketful of vomit by his side. He was a well-made but fat man of about forty years of age, and had, I believe, enjoyed very good health, but when I saw him he looked just like a man dying from unrelieved intestinal obstruction, or perforation of some abdominal viscus. His eyes were sunk and his face was pale and slightly jaundiced. His pulse was quick and feeble; the tongue was dry; and, above all, he had that terrible expression of anxiety that we are accustomed to associate with acute abdominal disease. The bowels had been confined from the first, and the urine was scanty. I turned down the bed-clothes with the confident expectation of finding the abdomen distended and tympanitic, but to my great astonishment there was no distension. The large intestine was obviously empty, and beyond a slight fulness in the epigastrium, which was not tender, there was no abnormality. It seemed a paradox that a man should present all the symptoms of intestinal obstruction and yet none of the signs. I could only conclude that the obstruction did exist but was very high up in the duodenum, or possibly the jejunum. There seemed only one possible explanation—viz., that a gall-stone had become impacted and was giving rise to the trouble. To this view some colour was given by the very sudden onset of the pain and by the slight jaundice. His friends were warned of the probable fatal result of all treatment, but were advised that the only hope lay in immediate operation. With this in view he was removed to the hospital, and Mr. W. F. Haslam, to whose kindness I am indebted for the following notes taken at the time of operation, opened the abdomen about four hours after admission. "The abdomen was opened by an incision in the middle line above the umbilicus, and coils of pale and very contracted small intestine were seen. On following the small intestine upwards this appearance was found to be present almost as far as the commencement of the jejunum. Here the intestine gradually increased in size and its colour changed from a pale slate colour to a redness that suggested inflammatory effusion into its walls, and the last piece of intestine that could be seen was of rather more than normal diameter, and its walls felt thickened. There were no signs of the intestine having been subjected to pressure by any constricting band, nor was anything found that could have pressed upon it. The lymphatic glands in the mesentery were greatly enlarged and in places calcareous, but they were not causing any pressure on the



Hosted by Google

intestine. As the lumen of the intestine was found free from obstruction, and there was evidence of the duodenum being also free, the abdomen was closed. Operation gave no relief, and he died in a few hours."

Necropsy.—The body was found to be very fat, but bore no other morbid appearance. There was an operation in the mid-abdominal line. The thoracic organs showed no lesion of importance. There was peritonitis affecting the third part of the duodenum, there being much injection with deposit of lymph in a thin granular layer. There was some dark, opaque, greenish fluid in the cavity. The stomach was slightly distended. The mucous membrane was very catarrhal and showed ecchymoses in places and even acute gastritis in patches. Microscopic examination showed very marked catarrh of the mucous membrane, with considerable cellular infiltration of the sub-mucous and muscular coats. This infiltration was not evenly distributed, being more marked in some places, so that areas were seen under the microscope which contained great numbers of leucocytic cells and even fibrin. There was great engorgement of the vessels, with cell exudation in their neighbourhood. There was some dilatation of the duodenum and the wall was very much thickened. There was intense engorgement of the vessels and inflammation of the peritoneal surface, the mucous surface showing many ecchymoses. There was no obstruction of the duct, which was found to be quite pervious. In the cellular tissue (extra-peritoneal) there was some infiltration with opaque grey fluid. Microscopic examination showed intense inflammation of all the coats of the duodenum, consisting of fibrinous exudation into their tissues with a very marked amount of cellular infiltration as well. These cells were of various characters and sizes and very many of them showed karyokinesis. All the vessels were greatly engorged, and round them was a very marked cellular exudation. There was marked catarrh of the mucous membrane, and the cell infiltration mentioned above extended as far as the bases of the villi, and in some places seemed to have quite obliterated Brunner's glands; in others these glands could be seen lying in a mass of exudation and their epithelium appeared extremely catarrhal. A section was made showing the passage of the pancreatic duct through the wall of the duodenum, and its examination showed marked catarrh of the epithelial coat. The jejunum and ileum showed no lesion. There was nothing suggestive of intestinal obstruction. The iliac mesentery contained a cretaceous nodule of considerable size. All the mesentery seemed loaded to an abnormal extent with fat. The large intestine showed no lesion. The liver weighed 68 oz. The organ was enlarged, brown-red in colour, and the lobules were very distinct. There was no abscess formation or other lesion. The gall-bladder contained a single large cholesterine calculus and encysted cholesterine was found in the mucous membrane. Microscopic examination of the liver showed some fatty degeneration of the cells. The pancreas weighed 8½ oz. The organ was enlarged, soft, and of a peculiar greasy feeling at the head; towards the tail it seemed unaltered. The surrounding cellular tissue was infiltrated by an opaque grey fluid similar to that found outside the duodenum. This infiltration seemed to penetrate the pancreas, passing into the interstitial tissue, but forming a soft, almost putty-like exudation, which gave to the head the peculiar greasy feeling and swollen appearance already mentioned. Almost all the lobules of the head portion were surrounded by this substance. The glandular portion also appeared to be swollen and slightly translucent. Microscopic examination of the head of the pancreas showed that all the interlobular septa were infiltrated by fibrinous exudation in which were cells in greater or less proportion showing proliferative or destructive changes. In some places these cells were extremely granular and stained badly, in others their nuclei were more distinct. In more affected portions these cells appeared to have invaded the gland acini, and the glandular epithelium showed necrotic characters. Beyond this it seemed merely swollen. In the less severely affected parts there was no infiltration of the gland tissue by the cells, the exudation being confined to the interstitial portions of the pancreas. In many places this connective tissue showed, not infiltration by exudation, but marked proliferation, and the walls of the ducts and even those of the vessels were much thickened. The duct epithelium showed distinct catarrhal change in these situations. On passing towards the middle of the pancreas these changes became much less marked and examination of the tail end failed to show any morbid condition, there being no exudation into the connective tissue or even proliferation of its cells. The gland tissue also appeared to be quite healthy. The right kidney weighed 6½ oz. and the left 6¾ oz. The organs were very mottled and the vessels very engorged. The cortex was swollen. The capsule stripped fairly well. The pelves were healthy. Microscopic examination showed some catarrh of the tubules. The suprarenals were small, flabby, and very pigmented. On microscopic examination they showed fatty degeneration. The spleen weighed 9 oz., was soft and pultaceous. Microscopic examination showed no special characters.

CASE 2.—The second case, which I have the kind permission of Dr. E. Rickards to make use of, was almost identical in its history and similar in its treatment and result.

Necropsy.—The body was also found to be very fat. The peritoneum showed some inflammation over the anterior surface of the liver and round the pylorus, being slightly opaque and dull. This seemed to be due to extensive infiltration of the retro-peritoneal tissue by opaque brown-grey fluid, there being at the same time considerable cellulitis with deposit of greasy, pultaceous material similar to that found in the first case. There were areas of "fat necrosis" on the great omentum and other parts of the peritoneal surface in the neighbourhood of the pancreas. The pancreas was much enlarged (8½ oz.), and showed appearances very similar to those found in the first case, only in a more marked degree, the same pultaceous infiltration being found. There were, however, areas showing necrosis in the most affected portions of the head, together with small hæmorrhages (see illustration). As in the first case, the head of the pancreas was the

Section of pancreas near head, showing inflammatory infiltration, hæmorrhages, and small patches of necrosis.

portion showing the most intense changes, the tail being comparatively unaffected. The microscopic appearances were also the same, except for the presence of necrosis and hæmorrhages. The duct also showed considerable catarrhal change of its epithelium. The stomach showed much more severe changes than in the first case, being more hæmorrhagic, and there even seemed to be actual necrosis of the mucosa. The microscope confirmed these changes. The duodenum also was acutely inflamed and showed much swelling of its coats, and the same intense infiltration as described in the first case was found. The spleen, liver, suprarenals, and semilunar ganglia showed no important changes, the latter even appearing quite healthy.

CASE 3.—The third case was that of a stout woman, aged sixty-three years, under Mr. Heaton's care in the General Hospital, Birmingham. When admitted she complained of pain and distension of the abdomen, with constipation and vomiting. The duration was five days. Five days ago the patient had pain in the right loin and iliac fossa, spreading across the abdomen. Her bowels were opened on that day. Later in the day she began to vomit. Since then she had

Hosted by Google

had constipation with increasing distension of the abdomen and pain. The pain, however, had been rather less than at the onset. She had passed urine normally. Notwithstanding the stoutness of the patient, the tissues were firm and not flabby to the feel. The skin was slightly yellow. The face was drawn and rather anxious in expression. She looked ill. The tongue was large, moist, and furred in the middle. The temperature was 99° F. The pulse was fairly good. The abdomen was large, distended and soft; there was no tenderness. On percussion, it was tympanitic anteriorly, duller in the flanks, more expecially on the right side. There was no fluid. There was discolouration of skin round the umbilicus, but no signs of hernia, or anything abnormal on palpation. The patient had vomited more or less continuously since the first onset. The vomit, said to have been ordinary at first, was now a fæcal and dark brown fluid. The patient stated that she had had a somewhat similar attack two years previously, but not so severe. She had not suffered from chronic constipation. On examination per rectum nothing abnormal could be felt. The patient was put under an anæsthetic. An incision was made in the middle line, the peritoneum opened, and the bowels exposed. The intestines were not much distended, and appeared rather redder than normal. There was no sign of inflammation in the right iliac fossa. No strangulation or obstruction was found. The patient got weaker and weaker during the operation, with fæcal vomiting, and died soon after its completion.

Necropsy.—The body was extremely fat. On the peritoneal surface were scattered patches of a grey colour, about ⅛ in. in diameter, and evidently areas of fat necrosis. There was some fibrous thickening round the pancreas as from some former inflammation. The pancreas was enormously enlarged and contained large extravasations of blood, there being patches of well-marked necrosis outside the areas of hæmorrhage as well. This condition involved the whole organ, and outside the pancreas there was also hæmorrhage, this appearing to extend down in the retro-peritoneal tissue almost into the pelvis. There was a cystic cavity at the upper margin of the pancreas containing about an ounce of bloody, brownish fluid. The duodenum, though compressed, was not inflamed. The other organs showed no special change.

In the three cases bacteriological examination of the tissues of the pancreas and the fluid contained in the surrounding cellular tissue showed the presence of micro-organisms of different character. One of the most distinctive was a bacillus somewhat slender, with rounded ends, and which does not stain by Gram's method. Bacterium coli commune was also obtained by culture, especially from the fluid surrounding the pancreas and extending down behind the colon. These cases are, therefore, almost identical in their morbid anatomy, the only difference being of degree. Taking into consideration the manner in which the stomach and duodenum showed intense inflammation with involvement of the head of the pancreas—i.e., the adjacent portion—the tail practically escaping, the question may be raised as to whether we may not have to deal with an infective gastro-duodenitis, extending into the surrounding tissues. The manner in which the retro-peritoneal connective tissue showed infiltration and inflammation obviously from extension downwards by gravitation from the seat of the most severe lesion round the duodenum at once suggests some infective condition, and the abundance of micro-organisms in all the affected parts is of great importance. That the pancreas is not necessarily the primary organ affected is very probable, and from its situation and texture it would be readily affected by any infecting organism, either from the pancreatic tissue or by way of the duct. As this latter opens directly into the duodenum it is plain that any infecting organism could find a way into the organ. On the other hand, in many cases the pancreas seems to be the only organ affected, as in Case 3.

Here, then, we have a group of three cases which during life were thought to be characteristic of intestinal obstruction, or at least so nearly characteristic that, though the condition of the patients was clearly desperate, it was felt not to be right to withhold from them the chance that laparotomy might give. In my own case there was no general distension; this was present in Mr. Heaton's case, and the abdomen was tympanitic; but as a rule in recorded cases no general distension is present, and it may be possible that this distinction will help us in arriving at a diagnosis in the difficulty such a case presents. Fitz divided his cases into the following groups: (1) pancreatic hæmorrhage; (2) hæmorrhagic pancreatitis; and (3) acute pancreatitis which might stop short of or reach a gangrenous condition. Pathologically our cases correspond in inverse order to these divisions, but clinically no such division is possible, as it is only when the shock becomes very great or symptoms of intestinal obstruction occur that the case, as a rule, comes under medical observation. There are, I believe, no pathognomonic symptoms which can lead one in the present state of knowledge to diagnose or even suspect the presence of pancreatitis before the changes become pronounced and the condition hopeless.

In the case of very great hæmorrhage (Case 3) there were evidences of old adhesions at the back of the pancreas, and therefore our ignorance of the earlier stages of the disease may be only temporary, and we may argue from a fact like this that there had been an abortive or slight attack of the disease five years before the fatal attack. It would be the greatest unwisdom to disturb ourselves and alarm our patients by the suggestion that pain in the epigastrium and vomiting might mean a rapidly fatal disease, but the persistence of these symptoms without adequate cause should certainly in some cases excite very great apprehension. When we ask ourselves what all the fatal cases of pancreatitis have in common besides the pancreatic lesion, we find that it is neither sex, occupation, nor previous history of illness. It is not even, as we might expect, recent gastro-duodenitis, for there are several cases of large pancreatic hæmorrhage recorded in which death occurred suddenly and without warning by symptoms. In every case, however, the patient has been fat, and in a large proportion of the cases has become rapidly fat, and showed on post-mortem examination a heavy, fat omentum. In addition, every case in which proper examination has been made has shown the presence of numbers of differing kinds of bacteria. It is probable that in these two conditions we have both a predisposing and an efficient cause for the disease. Anything which delays the products of digestion in the duodenum, especially if these be decomposing, will increase the liability of infection of the pancreas, and according to the virulence of the infection will be the acuteness of the disease and inversely the duration of life. One cannot look at the duodenum without thinking that its shape, while necessary for delay in the passage of food in order to get due admixture of bile and pancreatic secretion, may become a source of danger if any addition to the delay in the passage of the products of digestion or decomposition arises, as must result from the presence of a large amount of omental and mesenteric fat, and therefore it is that epigastric pain in fat people, or those who are somewhat rapidly becoming fat, assumes an importance both from the view of treatment and from that of prognosis. No one can see a case of acute pancreatitis without being oppressed by the horror of its suddenness, of its severity, and its hopelessness. A sudden but sometimes fearful pain in the upper part of the abdomen, shock which may be so great as to kill the patient with the rapidity of cerebral hæmorrhage, and vomiting which continues unrelieved until stopped by death—these constitute a trio of symptoms before which we are hopeless. But is there nothing we can do to prevent their occurrence? I fear not if, as seems most likely, the disease is due to infection by a pathogenic organism. It is possible that by treating vigorously gastro-duodenal catarrh, and by means of salol and other disinfectants rendering the duodenum an unsuitable habitat for bacilli, we may diminish the likelihood of pancreatic infection, but until the symptoms of pancreatitis occur we can only guess at its existence, and its non-occurrence cannot furnish an argument that our treatment has averted it. When once the disease has commenced, no treatment has been effectual. In common with nearly all recorded cases, those in the General Hospital, Birmingham, were treated by laparotomy, and to my thinking properly so. There must be an element of doubt, even if pancreatitis be suspected, and the doubt that must exist in every case as to whether or not we have to deal with intestinal obstruction from the impaction of a gall-stone or from other causes will justify operative interference when relief by drugs has been despaired of.

Birmingham.

THE USE OF CALF LYMPH.—The Horsham board of guardians has decided to supply its medical officers with calf lymph for the public vaccination of children subject to the consent of the Local Government Board. Most of the medical officers of the board wrote in favour of such a plan.

THE MALIGNANT TUMOURS OF INFANCY, CHILDHOOD, AND YOUTH.

BY W. ROGER WILLIAMS, F.R.C.S. ENG.,
FORMERLY SURGEON TO THE WESTERN GENERAL DISPENSARY; AND SURGICAL REGISTRAR, MIDDLESEX HOSPITAL.

(*Concluded from p. 1263.*)

RECTUM.

THE rectum is remarkable for the comparatively large number of cancers that arise from it during early life. Moreover, the earliest duly authenticated case of cancer hitherto recorded has been met with in the rectum. This is the case described by Stern,[193] in which an annular cancerous stricture of the rectum, causing obstruction, was met with in a girl only eleven years old. Right lumbar colotomy was performed, but she died six months later. At the necropsy a cylinder-celled cancerous growth was found, constricting the bowel, at 10 centimetres above the anus. More than a score of cases of rectal cancer, originating under twenty years of age, might easily be collected. I have notes of the following examples: Allingham[194] in a youth aged twelve years; Michaud[195] in a youth aged thirteen years; at fifteen years of age by Godin[196]; in a youth aged sixteen years by Quain and Busk[197]; in girls aged sixteen years by Pillon[198] and Schoening[199]; in a youth aged seventeen years by Cripps[200]; and in a girl of the same age by Schoening. The earliest age at onset within my own experience occurred in a woman aged twenty-one and three-quarter years: this was the youngest of 32 consecutive cases of rectal cancer in females. Of 32 similar cases in males the youngest was twenty-four and a quarter years. A few instances of rectal sarcoma have recently been published. In children fibro-cellular polypi, which often contain glandular structures, are of common occurrence in the rectum. These sometimes manifest sarcomatous properties, but much less frequently than do the somewhat similar growths in the vagina. Probably only a small minority of these rectal polypi are the outcome of embryonic aberrations similar to those that originate the vaginal polypi, and this may account for their comparatively innocent nature.

LIVER.

The number of cases of primary malignant disease of the liver that have been recorded as occurring in early life is very considerable. Such cases are much more numerous than I was aware of, until I specially studied the literature of the subject; and many of them are of congenital origin. These tumours are often described as "cancer," but I think there can be no doubt that this is a mistake. Birch-Hirschfeld reports that of 400 necropsies on newly born children primary malignant disease of the liver was met with in 2, and that in both these cases the disease was diffuse. The following example of hepatic myxo-sarcoma has come under my notice.

CASE 8.—The patient was a small, well-nourished girl, eight years old, with a large intra-abdominal tumour of three and a half months' duration. Laparotomy was performed. Incision into the tumour revealed a large cavity full of blood-stained fluid and gelatinous material; and on examination the disease proved to be a large, softening myxo-sarcoma of the liver. The morbid tissue was freely scraped away and the cavity drained. The patient made a good recovery; but some months later when I last saw her there was obvious recurrence. Histological examination of the substance removed revealed stellate anastomosing cells in a fibro-gelatinous matrix, with areas of small round cells in many places.

I have seen an almost exactly similar case in a young adult. Other examples of this form of malignant disease have been repeated by Meisenbach[201] in an infant aged four months, and by Cornil[202] at eight months. In some of the congenital cases the intra-abdominal tumour has been so large that it has caused difficulty in delivery. Instances of so-called cancerous tumours of this nature have been recorded by Noeggerath,[203] Kilian,[204] and Wedl.[205] In the two first-named cases the diseased liver weighed over 2 lb., the weight of the infant without the tumour being under 6 lb. De Ruyter[206] has met with congenital lympho-sarcoma in an infant ten days old, Parker[207] at three weeks, Lendruf[208] at four months, and West[209] at eight months. Pepper[210] reports "cancer" in an infant eight weeks old, Gross[211] "scirrhus cancer" in a male coloured infant aged three months, Gee[212] "alveolar sarcoma" at four months, Bahn[213] cancer at six months, Ollivier[214] "encephaloid cancer" at eighteen months, Weichselbaum[215] "malignant adenoma" at twenty months, Henoch[216] "medullary sarcoma" at two and a half years, Wolff[217] "encephaloid cancer" at three years, Tooth[218] "diffuse lympho-sarcoma" at five years, Leichtenstern[219] "cancer" at seven years, Kottmann[220] "cancer" at nine years, Deschamps[221] "encephaloid cancer" at eleven years, Pye-Smith[222] and Birch-Hirschfeld[223] "cancer" at twelve years, Roberts[224] "medullary sarcoma" at twelve years, Lewis[225] "encephaloid cancer" at thirteen years, and Henschen[226] "telangiectasic cystic cancer" at fourteen years.

PANCREAS.

Malignant disease of the pancreas is decidedly rare, and it is much rarer still to meet with such affections in early life. However, instances of congenital malignant disease—so-called "cancer"—have been reported by Arnozan[227] and Rokitansky,[228] and Kühn[229] has met with "cancer" in a two-year-old infant. Litten[230] has described an enormous sarcomatous tumour that arose from the pancreas of a male infant four years old and disseminated in the retro-peritoneal lymph glands, kidneys, mesentery, and intestines. The author claims that this is the first case of sarcoma of the pancreas ever recorded as such. Israel[231] has found "cancer" at thirteen years and Battersby[232] at fourteen years. According to my ideas the carcinomatous nature of the disease has not been clearly established in any of the foregoing cases. Of 15 cases of cancer of the pancreas collected by N. Moore[233] the youngest was aged thirty-one years.

SPLEEN.

When we consider the great functional activity of the spleen, its abundant blood-supply, and the unusually large proportion of cellular elements which it contains, it is not a little surprising that it so very seldom originates any form of neoplasm, malignant or otherwise. This immunity extends also, to a certain extent, to secondary neoplasms; for although the spleen is just as much exposed as the liver to the incidence of malignant dissemination, yet it very much less frequently originates secondary new formations. It seems not unreasonable to suppose that this comparative immunity of the spleen is in some way connected with its functional activity, which enables it to destroy and make away with cells manifesting malignant properties, whether these are derived from its own constituents or *ab extrâ*. I can cite only the following examples of malignant splenic disease in early life. Collier[234] in a child six years old found a peculiar tumour of this kind which Picou and Ramond[235] think arose from pancreatic "rests," such as they have shown to exist in this organ in a three months' human embryo, and to which they ascribe the origin of a case of primary malignant disease of the spleen investigated by them. Gaucher had previously reported a similar case. To this category the multilocular cystic tumour for which Thornton[236] extirpated the spleen of a young woman, aged nineteen years, probably belongs. Notta's[237] case of "cancer" of the spleen in a young infant may also be mentioned here; but we must remember that multiple cysts may arise in the spleen from included sequestrations of the peritoneal epithelium, of which Ribbert[238] has described an interesting case.

LYMPH GLANDS.

The lymph glands, like the spleen, seldom originate any form of malignant disease. Their relative immunity is, however, much less complete than that of the spleen. A considerable proportion of sarcomata of the lymph glands arise during early life—the retro-peritoneal, mesenteric, mediastinal, and cervical regions being the localities in which most cases arise. Examples of retro-peritoneal and mesenteric lympho-sarcomata have been reported by Bensuade[239] in an infant aged two and a half years, by Silcock[240] and Doernberger[241] in infants aged four years, by Guinon[242] and Gyrus[243] at five years, by McNab,[244] Morton,[245] and Stern[246] in children at various ages. Of 55 mediastinal lympho-sarcomata, Eger found 6 began under the age of twenty years, one of these being under ten years. Tumours of this kind have been met with in the posterior mediastinum by Money[247] in a male infant fifteen months old, and by Davies[248] in a youth aged eighteen years; in the anterior mediastinum by West[249] in a youth aged seventeen years; by N. Moore[250] in a youth aged eighteen years; and by Mott[251] in a young woman aged twenty-one years. Cases of cervical lymph-gland-sarcoma have been recorded by

Hosted by Google

Dalziel[252] in an infant of between two and three years of age; by Pughe[253] in a boy aged ten years; and I know of an instance in a boy aged eight years.[254] I have seen lympho-sarcoma of the parotid region in a woman aged nineteen years; and I know of an instance in which the sub-maxillary glands were affected in a youth aged nineteen years.[255] Maas[256] has met with sarcoma of the axillary glands in an infant; and O. Schmidt[257] with chloroma of the same glands in a young woman aged twenty years. An example of Hodgkin's disease in an infant, aged three and a half years, has been described by Allen[258]; and Hobson[259] has seen a similar case at four years.

LARYNX, THYROID, LUNG, &c.

Of 50 cases of cancer of the larynx collected by Butlin[260] only one originated under twenty years of age, and of 23 cases of sarcoma there was also only one under twenty years. The case of so-called cancer above referred to occurred in a three-year-old infant, and the case of sarcoma in a child aged seven years. Paul[261] has met with intrinsic sarcoma of the larynx in a boy aged twelve years, and with extrinsic sarcoma in a woman aged twenty years. Multiple papillomata of the larynx are very common in young infants, and they occasionally manifest malignant properties. Recurrence after removal is exceedingly common. These growths are often congenital. McAldowie[262] has reported a case of malignant disease of the lung—which he calls "cancer"—in an infant five and a half years old; West[263] has seen sarcoma in a boy aged eleven years; Hofmokl[264] sarcoma of the pleura in a boy aged three years; and Lepine[265] "cancer" of the pleura in a child aged ten years. An example of cylinder-celled cancer of the lung in a youth aged seventeen years has been described by Coats.[266] With regard to the thyroid, Zahn[267] has met with a chondro-rhabdo-myosarcoma in a fœtus. In a girl aged fifteen years Brindel and Liares[268] have demonstrated "epithelióme pavimenteux lobulé" of the thyroid, and Busachi[269] has found a similar affection in a youth aged eighteen years. The heterotopic epithelial elements in these cases probably originated from "rests" of the branchial clefts. In Kroenlein's[270] case of congenital "cancer" of the neck the disease most likely had a similar origin.

SKIN.

There are on record quite a considerable number of cases of malignant disease of the skin in early infancy, and even at birth. In a newly-born child Ritter[271] met with what he calls "a congenital cancerous polypus" of the tip of the nose; there were enlarged lymph glands in the sub-maxillary and parotid regions, which increased and caused death by asphyxia three weeks later. Although Ritter calls the tumour "cancer" his own description of its structure is much more like that of sarcoma. It is likely that the malignant disease in this case supervened in connexion with a congenital polypoid lipoma, such as Lannelongue[272] has described as occurring in this situation. Jolly[273] has met with angio-sarcoma of the base of the nose in a male infant seven months old. Selberg[274] has lately described an example of "cancer" of the skin of the scapular region in an infant aged six months, which was first noticed four weeks post-partum. The disease presented as a slightly ulcerated, knobby, walnut-sized tumour. The microscopical examination revealed in-growing inter-papillary processes and nests; and this was thought to justify the diagnosis of cancer, although none of the clinical signs of this disease were present. Holmes[275] had previously reported a somewhat similar case in an infant aged fourteen days (the part affected being the skin of the back of the neck), and Lukasiewig[276] in a child three and a half years old. The "sarco carcinomatous nodes" observed by Kaposi[277] on the faces of two girls, aged respectively seven and ten years, were evidently sarcomatous; and the same is true of very similar cases in children aged eleven and twelve years old that Esmarch[278] has described. Rüder[279] has met with analogous instances. In all these cases the malignant disease supervened on xeroderma. Neuhaus has lately reported an example of congenital sarcoma of the skin of the leg in a child two months old. Karewski and others have met with similar cases. Earle[280] mentions a case of "soot cancer" in a child aged eight years; and Curling[281] cites a case at fifteen years. As previously mentioned, I have met with rodent ulcer in a girl aged fourteen years; Bleck[282] and Hutchinson[283] have since reported analogous cases at about the same age. Braun,[284] in a girl of fourteen years has seen cancer develop in the scar of a burn of the scalp; the disease proved fatal by perforating the cranium. Curtis[285] has noticed a similar case in a child aged eight years. Sangster[286] has described an instance of malignant disease of the scalp in a youth aged sixteen years; Conner[287] sarcoma of the same part in a young woman; and Frerichs[288] cancer in a youth aged nineteen years. Examples of "calcifying epithelioma" of the skin have been published by Stieda and Malherbe; "adenoma" would be a more appropriate term for this disease. Janisch[289] has seen "hæmangio-endothelioma tuberosum multiplex" in a girl aged seventeen years, in whom the disease began in the skin over the sternum at the age of seven years; Nasse,[290] in a boy aged eleven years, met with multiple cheloid with contraction, the disease being of four and a half years' duration; instances of congenital cheloid have been reported by Volkmann, Bryant, and others. A congenital sarcomatous tumour of the right side of the face has been described by Charbon,[291] and Davies-Colley[292] has removed a fibro-sarcomatous tumour from the skin of the back of a youth aged sixteen years, which appeared to have started from a congenital lymphangioma. Instances of melanotic sarcoma of the skin have been met with by Gussenbauer, Denzler, and others.

BRAIN AND SPINAL CORD.

Of 34 primary malignant intracranial tumours, tabulated by a committee of the Pathological Society,[293] in 9 the patients were under twenty years of age; 1 case belongs to the first quinquenniad, 4 cases to the second, 3 to the third, and 1 to the fourth. The great majority of malignant brain tumours of early life are gliomata, most cases arising from the pons and its vicinity. Ziegler and Stræbe maintain that their formation is determined by developmental irregularities. Instances of this kind have been recorded by Pilliet at twenty-one months, Cayley[294] at two and a half years, by Chaffey[295] and Kidd[296] at six and a half years, by Goodhart[297] at nine years, by Chaffey[298] and Money[299] at eleven years, and by Beevor[300] at twelve years. Examples of cortical gliatoma have been described by Money[301] at five years, by Albertoni and Osler[302] at fifteen years, and by Keen at seventeen years. In the cerebellum sarcomatous tumours have been noted by Peabody[303] at three years, by D'Arcy Power[304] at five years, by Butlin[305] at eight years, and by Taylor[306] at nine years, &c. Of 17 intracranial tumours in early life tabulated by Mariage, 8 were cerebellar. Psammoma of the cerebellum has been met with by Beevor[307] in a boy aged eleven years, and of the choroid plexus by Ashby[308] in a boy aged three and a half years, and by Eve[309] in a youth aged nineteen years. Allbutt[310] has described villous papilloma of the choroid plexus in a girl aged nine years, and Douty[311] a similar tumour of the fourth ventricle in a youth aged seventeen years. Lancereaux,[312] in a girl aged fifteen years, found a large polypoid myxoma growing from the lining membrane of the fourth ventricle, which caused coma and death. An instance of small, round-celled sarcoma of the pia mater of the fourth ventricle in a girl aged fifteen years has been reported by Turner.[313] In a youth aged nineteen years Ransom[314] has demonstrated large, oval-celled sarcoma of the corpora quadrigemina, and Westphal[315] met with multiple sarcomata of the brain and meninges, in a girl aged fifteen years. An interesting case of adeno-sarcoma of the pineal gland has been recorded by Coats[316] in a youth aged thirteen years; the tumour contained cartilage, &c., and the author suggests that it may have sprung from the rudiments of the pineal eye. In the spinal cord Bastian[317] has found diffuse sarcoma of the pia mater in a girl four and a half years old, and Schultz[318] in a girl aged sixteen years met with a similar condition. Instances of chloroma of the dura mater, &c., in children, have been reported by Lang and Aran.

EAR.

Very few cases of malignant diseases of the ear are met with in early life. The following interesting case of melanotic sarcoma has come under my notice.

CASE 9.—The patient was a rather pale, fair, red-haired youth, aged fifteen years, with a small, hard, shotty, black lump on the back of the edge of the left auricle at the junction of the lobule with the helix. In the course of eight years this lump increased to the size of a horse-bean; and shortly before this a second small black lump formed on the external surface of the ear, at the junction of the lobule with the tragus. There was then no obvious enlargement of the adjacent lymph glands. No wart, mole, or other congenital blemish of the

Hosted by Google

part previously existed. The disease supervened spontaneously, without any injury or other known cause. It was freely excised, and the wound healed quickly. Shortly afterwards, however, a lymph gland below the ear became slightly enlarged. I saw him again eighteen months later, when the gland below the ear was of the size of a walnut, and there was a pea-sized nodule of recurrent black growth in the scar at the margin of the helix. The recurrent nodule was extirpated, as well as the enlarged gland, and both proved to be melanotic sarcoma. Histological examination of the primary growth showed a delicate, fibrillar, reticular structure, in the meshes of which were embedded small rounded cells, charged with pigment granules. I failed to ascertain what ultimately became of him.

An instance of fibro-myxo-sarcoma of the left auricle in a young boy has been reported by Agnew.[319]

CASE 10.—In this patient the tumour was first noticed at the age of two years. It was excised one and a half years later, but recurred almost immediately. A further operation, two years later, was followed by equally speedy recurrence. In the course of two years the tumour, having attained the size of a walnut, was again extirpated, but there was recurrence soon afterwards. By the time the boy had attained the age of eleven years the tumour was much larger than ever. It was then freely extirpated, together with the whole auricle; but a small recurrent nodule appeared in the scar six months later. After this the patient was lost sight of.

Cases of sarcoma of the tympanum have been described by Schwartze[320] in a male infant aged three and a half years, by Milligan[321] in a girl aged eighteen years; and by Bryant in a girl ten and a half years old.

MISCELLANEOUS.

In a boy, aged fourteen years, subject to phimosis and warts from infancy, Pemberton[322] reports having seen "cancer" develop, but the diagnosis was not verified by histological examination and the adjacent lymph glands were not enlarged. Weir[323] has published an instance of sarcoma of the penis in a youth aged eighteen years; the glands of the groin were enlarged, but no microscopical examination of the tumour was made.

Sarcoma of the thigh has been noted by Dawson[324] at birth, and by Lunn[325] in a girl aged sixteen years; of the buttock in a lad, aged eighteen years, by Treves[326]; and of the lumbar region[327] in a girl aged eighteen and a half years.

In a six months' fœtus Zahn met with myxo-sarcoma of the cheek, which started from the "sucking-pad." Heymann,[328] in a girl aged seven years, saw a malignant bleeding polyp of the septum nasi.

Kramer[329] has described a fibro-sarcomatous "desmoid tumour" of the abdominal wall in a female child four and a half years old, which was of congenital origin; and Senger[330] in a male infant, has seen a large congenital sarcoma of the foot.

Malignant tumours of the salivary glands are occasionally met with in early life. A case of sarcoma of the parotid has come under my notice in a boy aged seven years, in whom the disease was of three months' duration. Prudden[331] has described a similar case in a boy of the same age, in which the tumour contained glandular elements and striped muscle. In a girl aged twelve years[332] and a boy aged fifteen years[333] examples of adeno-myxo-sarcoma of the parotid have also been reported. Isoner has described a case of congenital sarcoma of the parotid in a male child three months old, and he cites two similar cases.

Congenital spindle-celled sarcoma of the shoulder has been observed by Mandillon[334] and of the leg by King.[335] Kaufman[336] has described a case of congenital sarcoma of the umbilical cord.

SUPERIOR AND INFERIOR MAXILLA.

A considerable number of cases of malignant disease arise during early life in connexion with these bones, most of them being myeloid sarcomata. I have collected notes of 25 cases arising under the age of twenty years; 7 of them originated from the superior maxilla and 14 from the inferior. Of the former group 2 were congenital, 1 occurred in an infant three and a half years old, 2 were between the ages of ten and fifteen years, and 2 between fifteen and twenty years. Of the latter group, 3 were congenital, 2 occurred in the first year, 5 in the age period five to ten years, 5 between ten and fifteen years, and 4 between fifteen and twenty years. This list includes 3 odontomes—1 in a boy aged ten years, and the other 2 in women aged eighteen years. It also includes 4 cases of round-celled sarcoma, 1 of round- and spindle-celled sarcoma, and 1 myxoma. Massin has not met with a malignant "enamel-organ tumour" of congenital origin.

BONES.

The skeletal bones rarely originate malignant tumours until the third quinquenniad, when a large number of cases arise. To this rule the scapula is an exception, for sarcomatous tumours not unfrequently spring from it at much earlier periods. Of 25 bone sarcomata in infants collected by Poinsot,[337] in 11 the scapula was the part affected. Instances have been published lately by Jacobi[338] (congenital), Targett[339] (at the age of six months), Morgan[340] (infant), Doll,[341] and Clark[342] (at the age of thirteen years). Sarcomata of the long bones are rarely met with in infancy. Of Gross's[343] 147 cases, only 3 arose during the first quinquenniad and 3 during the second; of 119 cases tabulated by Butlin and Colby[344] 3 belong to the first quinquenniad and 3 to the second; of 25 cases collected by myself, 2 belong to the first quinquenniad, 2 to the second, 15 to the third, and 6 to the fourth. The femur, tibia, humerus, and fibula are the bones most frequently affected, in the order stated. More than half the cases arise from the femur. Of 11 sarcomata of the femur collected by me the youngest occurred in a boy aged nine years, 5 belonged to the third quinquenniad, and 5 to the fourth. The lower end of the bone is the usual starting-point of the disease, which is generally of periosteal origin. Jacobi[345] has cited an instance of congenital sarcoma of the femur. I have met with sarcoma of the fibula in a girl thirteen and a half years old and in a boy aged fourteen years. Butlin[346] has described a myeloid sarcoma of the upper part of the tibia in a female child only four years old. A case of round-celled sarcoma of the radius has been reported by Lockwood[347] in a female infant aged eleven months. Bryant[348] has met with sarcoma of the hand in male infants fifteen and twenty months old; but it is not clear from his description whether the disease started from the bones or the soft parts. An instance of myo-sarcoma of the tuber ischii in a boy four years old has been described by Marchand[349]; and I know of a case of spindle-celled sarcoma of the acromion[350] in a youth aged fourteen years. Oppenheim,[351] in a male child three years old, found sarcoma of the seventh cervical and first dorsal vertebræ; and Riskorski,[352] in a girl aged fourteen years, has also met with a sarcomatous tumour of the spine.

MUSCLES.

Malignant tumours of the muscles in early life are almost unknown. I can cite only the following cases:—Marshall,[353] in an infant five months old, has seen a spindle-celled sarcoma of the calf muscles that was probably congenital; Bórard,[354] in a girl aged twelve years, met with sarcoma of the pectoralis major muscle; Barling[355] has reported alveolar sarcoma of the triceps in a young woman aged twenty years; and in a boy aged seven years Broca[356] found sarcoma of the sheath of the peroneal muscles.

MEDICAL MAGISTRATE.—His Excellency the Governor of the Cape of Good Hope has appointed Mr. Charles William Browne, additional Visiting Surgeon Aliwal North at Jamestown, Justice of the Peace for the District of Aliwal North.

THE NEW PORTSMOUTH HOSPITAL.—Mr. Keith Young has just prepared the plans suggested for the replacing of the present Royal Portsmouth, Portsea and Gosport Hospital by a more modern institution. The out-patients' department and the administrative block face the street, the latter connected with a ward of ten separate bedrooms. At the rear, and of course amply connected are four parallel wards of twenty beds each. The laundry is practically a block to itself. Two of the last-mentioned wards are first to be built on vacant sites, the remainder of the land being gradually cleared, and the present buildings replaced.

THE

PROGNOSIS OF PNEUMOTHORAX, WITH SOME STATISTICS AS TO MORTALITY AND DURATION, AND AN ACCOUNT OF A SERIES OF CASES OF RECOVERY.[1]

BY SAMUEL WEST, M.D. OXON., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN, ETC., TO ST. BARTHOLOMEW'S HOSPITAL; SENIOR PHYSICIAN TO THE ROYAL FREE HOSPITAL.

(*Concluded from page 1267.*)

B.—CASES OF RECOVERY AFTER SEROUS OR SERO-PURULENT EFFUSION.

CASE 6. *Pneumothorax with sero-purulent effusion of three months' duration.*—The patient, a man, aged twenty-two years, was quite well till three months previously, when he was attacked at night with sudden dyspnœa, so that he fainted. He got gradually worse, had some cough and expectoration, spat a little blood a few times, but only about an ounce at the most, began to sweat at night and to lose flesh. After a few days he got better, but was never well enough to go out. He remained in the same condition till a pain in the right side set in, which gave him a great deal of distress, so that after a few days' suffering he applied for admission to the hospital and was taken in, three months after the original attack. He was then found to be suffering from hydro-pneumothorax of the right side; the heart's apex was 1½ in. outside the left nipple line. As he lay in bed the whole of the front of the right side was resonant down to the margin of the ribs, the liver was displaced in the usual way, and the breath sounds were completely absent. The bell sound was well marked and so was succussion, which had a metallic character. There was a considerable amount of fluid in the chest, the level rising on the patient sitting forward up to the sixth rib in the nipple line. The temperature was slightly raised, reaching 100° or 101° F. every evening, but dropping to 99° at other times of the day. The patient was admitted on May 4th, and by the 22nd the side had become much more distended. The superficial veins on the right side of the thorax were greatly dilated, the course of the blood being from above downwards; so were also the veins of the right arm and the right side of the neck. It was evident that there was considerable intra-pleural pressure, although but little dyspnœa was experienced when the patient was lying still. The displacement of organs was extreme. On the 25th the side was aspirated. Air was allowed to escape as long as it would. The gas was analysed roughly and appeared to contain about 12 per cent. of carbonic acid. There were removed by the aspirator 41 oz. of a sero-purulent fluid with thick flakes, which was faintly alkaline, had a specific gravity of 1020, and became almost solid on boiling. The whole of the effusion could not be removed, as the patient began to cough and feel faint. The heart's apex returned after the operation nearly three inches in linear measurement and beat nearly under the nipple. The intra-pleural pressure was estimated and found to be on expiration + 13¼ in. of water, on inspiration + 6⅝ in. of water, so that there was a respiratory oscillation of nearly 6½ in. On examining the patient four days later it was found that no succussion could be obtained and that the bell sound was audible only over the upper part of the lung posteriorly as far down as the spine of the scapula; in the interscapular space some distant amphoric breathing was heard, but elsewhere, as before, no breath or voice sounds were to be detected. In the course of the next few days the fluid evidently was accumulating again; succussion, which was absent, returned, and the veins on the chest became more dilated, much as they had been before the paracentesis. On June 16th a second paracentesis was performed. The pleural pressure showed 8 in. of water with a respiratory variation of not more than 1½ in. No air escaped, but fluid came at once, and 22 oz. of sero-purulent fluid were removed, which, however, contained much less pus than on the previous occasion. On the 22nd the patient felt and looked better, and breathing

[1] A paper read before the Medical Society of London on Jan. 11th, 1897.

Hosted by Google

was greatly relieved. Succussion was absent. The amphoric breathing and bell sound were heard only about the upper part of the right interscapular space. By the 29th the apex of the heart had returned almost to its normal place. The bell sound was heard only in the supraspinous fossa, and in the upper part of the interscapular space. There was no succussion. The breath sounds were hardly different in character from those on the opposite side. Although there was a little dulness on sitting up it was evident that the fluid had almost entirely disappeared. One month later the following notes were taken: "The right side is a little contracted, but the movements are free, especially in the lower parts, though not quite so free as on the opposite side. Percussion is somewhat impaired over the whole side except at the apex back and front, where it is still somewhat hyper-resonant. Over this area the vocal vibrations, vocal resonance, and breath sounds are less than in other parts, and the bell sound is still audible. Elsewhere the voice and breath sounds are fairly normal. The heart's apex is hardly half an inch outside its normal place. The veins of the right arm, neck, and chest are still somewhat dilated." The conclusion was drawn that the pneumothorax had become limited to a very small area at the apex, and, although the percussion was a little impaired in the lower part of the chest, that the lung had expanded freely and was performing its functions normally. On Aug. 24th recovery seemed to be almost complete, except that the side was a little flattened and its movements slightly restricted as compared with the other. The voice and breath sounds, though somewhat rougher than on the left side, were otherwise not abnormal. The apex of the heart was in its normal place; the superficial veins were still a little dilated. The breathing was not in the slightest degree short even on going up and down stairs. The patient had gained flesh and, in fact, seemed to be perfectly well. This case was under observation in the year 1883. I saw the patient this year (1897), fourteen years later. The chest appeared to be absolutely healthy, and it was quite impossible to say that there had ever been anything the matter with it.

CASE 7. *Case of phthisis under tuberculin treatment; left pneumothorax; serous effusion; paracentesis; recovery; recurrence three weeks later without effusion; recovery.*—A man, aged twenty-four years, had suffered from phthisis for about nine months, and came into the hospital for the purpose of having Koch's treatment applied. He presented well-marked signs of phthisis at the left apex. The disease did not appear to be active, for the temperature was normal on admission, and though the injections of tuberculin were followed by the usual rise the temperature soon returned to normal and remained so. On May 5th the patient suddenly woke up in the night with a violent pain in the left side of his chest, but it extended, he said, from the left ear down to the margin of the ribs. The patient had a rigor and the temperature rose to 102° F.; the dyspnœa was considerable, so that the patient could hardly speak a word. Pneumothorax was found on the left side on May 14th. The following note was taken. The whole left side was tympanitic to percussion and the heart displaced far on to the right side. The bell sound was heard. At the base there was dulness, which in the recumbent position rose high into the axilla. Succussion was easily elicited. It was evident that besides the pneumothorax there was a large effusion, and on account of its rapid formation its nature was probably serous. Paracentesis was performed; a quantity of air escaped and 22 oz. of serum were drawn off. The specific gravity was 1018. The intra-pleural pressure on inspiration was + 4 in. of water, and on expiration + 5, with a respiratory oscillation of 1 in. The patient stood the operation well, but towards the end of it complained of pain in the precordial region, and on auscultation here pleuro-pericardial friction was heard. The heart returned nearly to its normal position. On June 1st, nearly a fortnight later, the following note was taken: "The heart's apex is now only about an inch from its normal position; the stomach resonance is distinct; the voice and breath sounds are heard everywhere, even down to the base behind, so that there can be but little fluid left. There is no succussion, and the bell sound is gone. It is evident that the air has completely disappeared and the fluid nearly." On June 8th the patient, after a violent attack of coughing, was seized again with pain in his left side. His breath became short and his temperature, which had been for some days normal, rose again to about 102°, and the bell sound returned in the middle part of the chest; that is to say, it was not obtained over the apex in front or at the base behind. On June 25th the following note was taken: "There is no succussion. From the physical signs it is evident that the impaired percussion behind is due to thickened pleura, and that the irregularity of the area in which the air is contained is due to the irregular adhesion of a partly expanded lung. Gradually the air was absorbed and the lung expanded as before, so that by July 10th the condition was very much that which the patient presented at the time of his admission into the hospital, with the exception that there was a little dulness at the base due to a thickened pleura." On July 24th the patient was discharged from the hospital in much the same condition as he had been on his entry.

CASE 8. *Pneumothorax of the left side in an apparently healthy person, without marked symptoms; considerable effusion spontaneously absorbed; complete recovery; six months later pneumothorax of the right side with much dyspnœa, without effusion, also with complete recovery.*—A well-developed, healthy-looking man, aged twenty-one years, was seized on Nov. 6th with sharp pain between his shoulders. Later in the day he complained of tightness in his chest and pain on breathing. These symptoms continued, so that he felt obliged to remain at home, though not in bed. He did during the succeeding fortnight actually go to work on two days in the week. The pain was worse at night, when he often felt hot and sweated, so that sleep was broken. He had lost flesh and strength rapidly, and, feeling ill, came to the hospital. With the exception of a little rheumatism now and then he had been in perfectly good health all his life, but a few days before the onset of the present illness he had got very wet and worked all day afterwards in his damp clothes. It transpired subsequently that on one occasion, one and a half years ago, the patient had once spat up a little blood, about two teaspoonfuls only. The patient came under observation eighteen days after the onset of his illness—viz., on Nov. 23rd. He was then found to have pneumothorax of the left side. The whole front of the side was tympanitic, with well-marked bell sound and succussion. A good deal of fluid was present, the level reaching up to the mid-axilla as the patient lay upon his back. The vocal vibration, vocal resonance, and breath sounds were almost absent over the whole side, but had a somewhat amphoric character on coughing. The temperature was 102° F. at its maximum, but for the greater part of the day a good deal below that. A needle was inserted and clear serous fluid obtained. As there were no urgent symptoms the patient was not interfered with, was kept in bed quietly, and treated on general lines. By Dec. 6th it was evident that the fluid was being absorbed and that there was great improvement taking place in the side, and on the 12th the following note was taken: "Outside but following the line of cardiac dulness, which is in its normal place, is an area of hyper-resonance about two inches in width. Elsewhere the percussion is somewhat impaired, but not anywhere dull. The vocal vibrations are heard and felt over the whole side, though not quite as distinctly on the right, but the breath sounds are hardly audible except in the upper part, and there is a little crepitation, probably friction, on deep respiration. There is now no longer any bell-sound or succession. The fluid has been almost entirely re-absorbed, the lung has expanded to a great extent above, though it is possible that in the hyper-resonant area a small amount of air still remains in the pleura. At any rate, over this area the bell sound was obtained a few days ago, though it is absent now." In a few days more even this hyper-resonant area disappeared and became practically normal over the whole side. On Jan. 19th the patient was discharged in all respects well, and except that the left side of the chest moved a little less freely than the right there was nothing to show that the chest had been affected.

About five months later, June 15th, the patient having in the interval been in good health, was seized in the night suddenly with severe dyspnœa and pain in the right side. He was admitted the next day and found to have pneumothorax of the right side. The dyspnœa, though urgent, was not extreme. General measures were adopted with relief, and on June 23rd it was obvious that the air was being absorbed, for the heart's apex was one inch nearer the sternum. On the 27th the liver had risen so that its upper border was at the sixth rib in the nipple line. On the 30th succussion was obtained, though only with difficulty, but there were no other signs of fluid. On July 4th succussion could no longer be obtained. On Aug. 1st the lung was in contact with the chest walls everywhere, and some friction

Hosted by Google

was heard at the base behind. Recovery was now complete. I have seen the patient lately—i.e., six years from his last attack—and he is perfectly well and the chest shows no signs of abnormality.

CASE 9. *Pneumothorax with serous effusion; paracentesis; absorption of air; partial recovery.*—The patient, a man, aged thirty-one years, was in good health except for a slight cough for six months, till eleven weeks before admission, when on rising one morning he found that he could not draw his breath freely and that he had a little pain in his right side. He tried to go on with his work, but found that he was unable to do so and had to take to bed, where he remained for a fortnight. After six weeks he was able to go back to work and do light work up to the time of his admission to hospital, though for the last three or four weeks he had found his breathing getting gradually more and more short. On admission he was found to have pneumothorax of the right side with a considerable amount of effusion. Percussion and bell sounds were well marked and there was well marked ægophony at the angle of the scapula. There was the usual displacement of the heart and liver. The fluid in the recumbent position reached up to the level of the fifth rib and on sitting up as high as the third rib. The temperature rose to 100° or 101° for three or four days after admission and subsequently fell to normal. Three weeks later paracentesis was performed and 80 oz. of clear serum were removed with great relief. The intrapleural pressure was zero. The organs returned nearly to their normal places. The patient was quite comfortable and suffered no distress from the operation. Gradually, however, the fluid re-accumulated, and when the patient decided to leave the hospital a month later his condition was much the same as on admission. After the patient had been out of the hospital for a month he returned to show himself. The lines of dulness were much as before, but there was no succussion and the breath sounds were audible all over the resonant upper part. The lower part of the chest contained a good deal of fluid, but no succussion could be elicited. The patient said that he had heard the splashing sound in his right side on leaving the hospital, but that it gradually decreased and had been absent for the last three weeks. The patient passed from observation, and his subsequent career is not known. The air had been all absorbed, and the case had become one of simple pleuritic effusion. However, as he felt well enough to do some work and would not submit to operation nothing further was to be done.

C.—CASES OF RECOVERY WITH PURULENT EFFUSION.

CASE 10. *Left pneumothorax; serous effusion; paracentesis; suppuration of puncture; empyema; sinus left; death from phthisis some months later.*—The patient, a man, aged forty-six years, had been ailing for twelve months with indefinite symptoms, when he was seized suddenly one night with very severe dyspnœa, with cough and pain in the left side. A fortnight later he was admitted into the hospital. He was suffering from very considerable dyspnœa, was cyanosed, and bathed in sweat; but after being in the hospital for a few hours he rallied. He was found to have pneumothorax of the left side with a large amount of fluid. Ten days after admission he was tapped and 74 oz. of clear, serous fluid were removed. The pressure was 9 in. of water. After the operation subcutaneous emphysema developed. Fourteen days later he was tapped a second time; the pressure then was + 4½ in. on expiration, + 1 in. on inspiration, with a respiratory oscillation of 3½ in. This time no fluid could be obtained. A short time afterwards the puncture suppurated and ultimately a communication was formed with the pleura, through which a discharge of thin sero-purulent fluid took place. From this time the patient slowly improved, the lung re-expanded, and after four months the patient left the hospital in a fairly good state of health with a discharging sinus in his left side. The lung had expanded fairly well over the whole side, but there were obvious signs of phthisis at the left apex. Some three or four months later he was re-admitted into the hospital because his health had been failing. The condition in the side was much as it was before; the lung had expanded over the greater part of the chest and the empyema cavity was quite a small one. As the discharge did not seem to be quite free the opening was somewhat extended with the knife and a drainage-tube put in. The phthisis made rapid strides, and a few months later, about twelve months from the commencement of the pneumothorax, it had involved both sides. Ultimately the patient died from phthisis.

CASE 11. *Left pyo-pneumothorax; discharge through the lung; partial recovery.*—The patient, a man, aged twenty-nine years, came under observation with left pyo-pneumothorax. No definite history of its onset could be obtained. The patient had been ailing for three years with a cough, which had been much worse during the last twelve months. He had occasionally spat a little blood and had suffered from night sweats and loss of flesh recently. The signs of pneumothorax were obvious, but succussion was not easy to obtain and the amount of fluid was not large. The left lung was adherent at the apex, where there were the signs of early phthisis. The symptoms were not in any way urgent and did not call for any active treatment. In a fortnight both the air and the fluid were reduced in amount, and the patient had gained 3 lb. in weight. Succussion also was less easy to elicit. The patient then began to spit up pus and this soon increased in amount. With the free expectoration of the pus the condition of the patient improved. Nothing further was done, and in six weeks' time the patient left the hospital greatly improved in general health. The signs of pyo-pneumothorax still persisted, though not quite to the same degree, and some ounces of pus were being expectorated daily. It would, I think, have been well to have operated on this case and laid the side freely open, but this was prevented by the patient's leaving the hospital.

I think we may fairly claim that pneumothorax is sharing in the diminished mortality of diseases of the pleura, and this I attribute to the better comprehension of the true nature and dangers of the disease and to its better treatment, especially during the early days of the attack, when the risk to life is greatest.

Wimpole-street, W.

ON

STENOSIS OF THE EXTERNAL AUDITORY MEATUS AFTER OPERATIONS FOR MIDDLE-EAR DISEASE.

BY A. G. MILLER, M.D., F.R.C.S. EDIN.,
SURGEON TO THE ROYAL INFIRMARY, EDINBURGH.

IN many of the earlier cases on which I have had to operate for septic middle-ear disease and its complications I have noticed that, after free drainage has been established from the wound behind the ear, there was a tendency to contraction of the meatus. In July, 1894, I showed to the Edinburgh Medico-Chirurgical Society a patient on whom I had operated for thrombosis of the lateral sinus, and in whom the meatus had contracted so much, during the period that the wound behind the ear was open, that it would hardly admit an ordinary probe. Looking at the circumstances of the case from the point of view that one adopts in the somewhat analogous case of stricture of the urethra complicated with perineal urinary fistula, it occurred to me that tying a tube in the meatus would cure the stenosis, drain the tympanic cavity, and hasten the closure of the wound behind the ear. Accordingly I got a tube made of flexible metal so that it could be bent to the normal curve of the meatus, and tied it in. When I showed the patient to the society the meatus was widely dilated, the cavity of the tympanum was clean and dry, and a sinus that had existed for some time behind the ear was permanently closed. The same method of treatment has been adopted with success in several other cases.

The treatment seems to me to be rational and on the lines of surgical principles. First, there is contraction of a normal canal, partly due to inflammatory thickening, partly to non-use, the discharge being drained from the tympanum mainly if not solely (at first) by the free wound behind the ear. Secondly, a perfect cure cannot be effected so long as the meatus remains stenosed. I take it that one of the most important principles in the treatment of septic middle-ear disease is a permanent free drain—permanent as well as free, the appropriate permanent opening being necessarily the normal external auditory meatus. Thirdly, an abnormal fistulous opening will not close permanently so long as the normal canal is constricted. I have seen many cases in proof of this in which the establishment of a free drain from the meatus has brought about the closure of a mastoid fistula even when it was neither expected nor

Hosted by Google

specially sought for. Fourthly, the best route by which to examine and treat the middle ear must always be the normal opening. So long, therefore, as it is stenosed it will be impossible to perform either of these procedures properly. Consequently, given a case of middle-ear disease in which there is stenosis of the external auditory meatus it must be dilated before the case can be properly treated or permanently cured, and the lodgment of a metal tube is an appropriate way of dilating the meatus.

How does this contraction of the external auditory meatus occur? In my experience there are two classes of cases in which contraction is met with and in which treatment with the tube is advisable and appropriate. 1. Cases in which from neglect the meatus is choked with discharge, and also contracted in consequence of thickening of the walls from inflammatory changes. In such cases syringing is impossible, there not being a sufficiently large channel for the lotion to flow both in and out, and an operation may be necessary to obtain a sufficient opening for syringing and for drainage; but in others, if operative interference be not otherwise indicated, dilatation of the meatus may be sufficient. For these latter the tube is appropriate. 2. Contraction of the meatus occurs also in quite another way. An operation has been performed to obtain access from behind the ear to the mastoid antrum or tympanum. The opening is made very free, and both syringing and drainage are better conducted through it at first. The meatus is forgotten, and as it is not used it contracts, and when the time comes when it ought to resume its function of being the main, or rather sole, medium of communication with the middle ear it is found to be contracted and therefore inefficient.[1] This result occurred not infrequently in my earlier operations; hence my devising the method of draining by the tube. For the last year or two I have not been troubled with contraction of the meatus, for I have always made packing of the meatus an essential part of the treatment of each case from the day of the operation.

There is another class of cases — perhaps the most common of all—in which the tube will be found useful. I allude to those that are treated at a hospital till they are almost well and are then sent or taken home with instructions to carry on the treatment, syringing or otherwise, but are brought back after a time much worse than when they went out.[2] The explanation is the common and usual one—viz., that the parents being ignorant and careless do not carry out their instructions properly, or neglect them altogether. In consequence one has a condition of matters very similar to that which I have described in the first class of cases. The special advantages of the tube in these last are that it is visible and so attracts attention, and therefore is not likely to be forgotten; besides, it is easily removed, cleaned, and re-inserted.

Some objections may be brought forward. 1. Why should not syringing of the tympanic cavity be sufficient? My answer is this: In the first place, if the meatus be stenosed efficient syringing by it is not possible. Again, the tympanic cavity may certainly be kept clean and clear by syringing from an opening behind the ear, but permanent relief cannot be secured so long as the meatus is not the principal medium of drainage. In other words, if there be stenosis of the meatus, syringing or draining by the meatus cannot be brought about, and inability to drain freely by the meatus precludes the possibility of effecting a permanent or satisfactory result. 2. Some have told me that the tube is difficult to clean, becomes choked, or causes pain, and therefore has to be removed. To these objections I answer that the tube is easily cleaned and manipulated being of metal, consequently it ought never to become choked. If it causes pain, that must be because it is too long, too large, or not of the proper curve; but these defects are easily remedied because the tube is of soft, flexible metal.[3]

The manner in which I employ the tube is as follows: The tube is about one and a quarter inches in length, with a flange which has two perforations to which tapes are fastened, so that it can be tied in. The diameter of the tube is from one-sixteenth to one-eighth of an inch, according to circumstances. The bore is made as large as possible so as to aid drainage. A small strip of gauze or thread of worsted is lodged in the tube, and this by its capillary suction acts as a syphon and aids in the drainage of the tympanum if the discharge be watery enough. I have seen the pus falling drop by drop from the gauze in some cases. This strip of gauze should be taken out and renewed daily or twice a day, which makes certain that the tube does not become choked. Each time that the tube is removed the tympanum may be syringed, but in many cases this is hardly necessary, the tube being sufficient to keep the middle ear dry. The gauze or worsted should project slightly from each end of the tube, and should not fit it too tightly.

Edinburgh.

[1] I have seen this occur even when there was free communication and lotion could be injected from the opening behind the ear to the meatus.

[2] In a hospital such as the Edinburgh Royal Infirmary, where there is a great demand for beds, it is impossible to keep patients in long enough (often many months would be necessary) to ensure perfect cure.

[3] Rubber tubing is not suitable, because it very quickly becomes septic and irritating, and because it cannot be tied in.

ON THE ANÆSTHETISATION OF CHILDREN.[1]

BY GEORGE ROWELL, F.R.C.S. ENG.,
SENIOR ANÆSTHETIST TO GUY'S HOSPITAL, ETC.

THE interest and importance of this subject is such as to need no emphasis, and I am the more encouraged since I believe that the particular method which it is the chief object of this paper to describe possesses such advantages over the ordinary employment of chloroform on children as to render it worthy of a trial. Comparatively little literature upon the use of anæsthetics on children exists, doubtless because such patients take anæsthetics very well. It was early found that children were easier to manage under chloroform, and less likely to die than adults; hence chloroform has to a large extent kept its place as the usual anæsthetic for children. As the most remarkable instance with which I am acquainted of the marked tolerance of children to anæsthetics, I may perhaps mention the case of a strong boy, aged seventeen months, whom I once kept anæsthetised for six consecutive hours, while a Macewen's long intubation tube was kept in position. It was necessary to keep him well under, for if the laryngeal reflexes were allowed to return, his breathing would become seriously interfered with. He had chloroform for an hour or two down the tube, and for the remainder of the time a mixture of chloroform and ether. He was fed twice with nutrient enemata, and in less than half an hour after I left he was playing. After-effects were absent.

It is well-known that the percentage mortality of chloroform in children is much below that in older patients; but there is at the present time no reason for supposing that symptoms dangerous to life do not occur as often in children as in adults under its use. It is, however, a well-recognised fact that children displaying such symptoms are far more amenable to the ordinary methods of restoration than are adults. Dr. Leonard Guthrie, in a valuable series of papers published a few weeks ago in the *Clinical Journal*, alludes to the greater proportional vitality of young children as compared with adults, to the natural elasticity of a child's chest walls, and to the stronger condition of the heart as probable explanations of the reason why this is so. Another difference between children and adults is, that in the latter one-half or more of the recorded chloroform fatalities have occurred during imperfect anæsthesia. Children are not so liable to depression of the circulation from the causes that operate in imperfect conditions of anæsthesia, and I believe that the cause of death from chloroform in children is almost invariably an overdose. One cannot feel that in experienced hands chloroform is an improper anæsthetic for routine use in children. But this is not enough. The question is, Is there a better method for general purposes? To recall some facts against chloroform. THE LANCET Commission on Anæsthetics recorded 33 deaths[2] in children under ten years of age; Dr. Hewitt quotes Comte's deaths—21 in children out of 232 collected; and Dr. Guthrie, although he records no death in 6000 cases, yet says that even with the greatest care dangerous symptoms will occasionally happen. In 260 of these cases, of which he preserved full

[1] Abstract of a paper read before the Harveian Society on April 29th, 1897.

Hosted by Google

notes, 20 showed signs of danger, in 14 the danger was slight, but in no less than 6 "the symptoms were most grave, necessitating prolonged artificial respiration and other restorative measures."

Let us now briefly consider the other means at our disposal for anæsthetising children. Pure nitrous oxide gas is impracticable save for very short operations, such as the extraction of one or two temporary teeth. Gas given with small quantities of air is, however, a valuable agent in certain operations. For opening superficial abscesses, manipulations of joints, and more especially for tenotomies and divisions of fasciæ, this method is all that is required. In such cases the face-piece is kept applied, and inspirations of air are admitted occasionally through the stop-cock in just sufficient quantity to prevent the development of asphyxial symptoms. One cannot attain flaccidity by this method, but it possesses the advantages of safety and freedom from after-effects. I have often kept children anæsthetised with gas and air for five or six minutes for short orthopædic operations. Gas with oxygen is the most suitable anæsthetic for children in dental cases, and it possesses the advantage over gas and air, in the short operations alluded to, that asphyxial symptoms are extremely unlikely to happen, and that a greater degree of muscular relaxation results. It is an ideal anæsthetic for the removal of tonsils with a guillotine. One troublesome symptom that I have observed with gas and oxygen, in four or five cases amongst some thousands, is the occurrence of vomiting while the administration is proceeding. This is unlikely to occur before three or four minutes have elapsed, but when it does it is very troublesome, as it necessitates the withdrawal of the anæsthetic for a time. I have used gas and oxygen for as long as ten minutes for moving stiff joints in the case of a boy aged thirteen years. So far as I know, Mr. Woodhouse Braine was the first advocate of ether as an anæsthetic for children, given upon cones of lint. Dr. Hewitt, in his book on the subject, alludes to this, and states that he had used the method himself, the youngest of his patients being fourteen days old—a circumcision. When I first paid particular attention to the subject I used this method several times, but was not satisfied with the results. Ether is a much more irritating vapour than chloroform, and one either had to spend a considerable time in inducing sufficient anæsthesia for the operation, or, by giving it in larger quantities, to risk the production of an unpleasant amount of straining, holding the breath, swallowing, coughing, and struggling—disagreeable reflexes excited by the strong vapour. When gas is used to induce anæsthesia this difficulty is overcome, and, speaking generally, the combination of gas and ether is the most desirable means of anæsthetising children above the age of five or six years. The advantages of rapidity of action, safety, and the minimum amount of unpleasantness to the patient can hardly be over-estimated; but the drawback of this method is that it requires considerable experience to attain the best success, chiefly because children taking gas develop asphyxial symptoms rather suddenly, which may make it necessary to discontinue the administration for the time. The A.C.E. mixture is well taken by children. Its administration need not differ from that of chloroform, except that if the child is strong the vapour given off from a single fold of material is not powerful enough for ease in managing the patient. Its advantages over choloroform are that the breathing is more audible, that one is better able to estimate the degree of anæsthesia of the patient at any particular moment, and that there is less likelihood of dangerous symptoms occurring. Compared with ether, its disadvantage lies in the fact that occasional depression of the circulation takes place under its use. The A.C.E. mixture is always to be regarded as diluted chloroform, and while it is more stimulating than pure chloroform, yet it is more likely to excite interference with respiration; an undesirable state of things with chloroform in the blood. Dr. Hewitt recommends the A.C.E. mixture for inducing anæsthesia, and ether to maintain it, given by means of a Clover's small inhaler. This method I have found to answer very well; but I do not think it is so good, either in theory or in practice, as the method I shall shortly describe, of the A.C.E. mixture followed by ether given by the open method throughout. Nevertheless, a change to the closed method, either using a Clover's or an Ormsby's bag, can be made with advantage whenever difficulty is experienced in maintaining proper anæsthesia with ether by the open method.

The difficulties of inducing anæsthesia by ether have already been alluded to. But anæsthesia being once established, it is much easier to maintain it at its proper depth with ether than is the case with chloroform. Mr. Braine's test of this depth, published in the *Practitioner* for October, 1896, lies in the fact that a child is able to grasp the administrator's finger until well under, so that, keeping his finger in the patient's palm, when he finds the patient's fingers become quite flaccid he considers that a proper degree of narcosis has been induced. Now a well known difficulty in the administration of chloroform is to distinguish a condition of relaxation, quiet breathing, small pupils, fixed globes, and absence of lid reflex, which is allied to deep sleep, from a similar group of symptoms which indicate a considerable depth of anæsthesia. Mr. Braine's test would be valueless in this difficulty. There is, however, no such doubt as this with ether, for the ether vapour tends to awaken the patient from such conditions. When a fresh amount of ether is applied, the sudden partial return of certain reflexes is often seen, and therefore without hesitation it may be said that flaccidity of muscles indicates a considerable depth of ether anæsthesia if the patient is breathing an ether vapour at the time. But I am bound to say that I find in practice that such a degree of flaccidity as Mr. Braine describes often exists while the child is able to move when the incision is made. The lid reflex is also notoriously unreliable in children. However, there is one test of the depth of anæsthesia under ether which is certain and invariable. I allude to the absence of reflexes connected with the act of respiration when a fresh ether vapour is applied. If at any time during anæsthesia, however produced, a fairly strong ether vapour be suddenly applied, and neither coughing, swallowing, straining, phonation, nor held expiration takes place during the next few respirations—in short, if the rhythm of breathing is unaltered, it can be regarded as absolutely certain that the child is ready for any operation. It is upon the recognition of this fact that the method advocated is based.

When I first held a teaching appointment at Guy's Hospital I spent one afternoon a week in the out-patient department, where many cases of children requiring operation, usually for phimosis, nævus, or abscess, attended on each occasion. The anæsthetics were administered by students, and it was our practice at first to rely mainly upon the A.C.E. mixture. In order to demonstrate the degree of anæsthesia existing at different times, I would often pour a drachm or so of ether upon the sponge, and we soon found that children who had breathed ether after the A.C.E. mixture displayed favourable symptoms. Their colour was bright; their breathing was audible, regular, frequent, and deep, more than counteracting the stertor and mucus that they sometimes exhibited; and (a most important consideration) they emerged slowly from the anæsthesia when the inhaler was removed for half a minute or so. In this way was gradually evolved the method to be described, which I have used extensively myself, and have watched students use many hundreds of times. The apparatus required is a Skinner's mask, or for small children a mask made from the corner of a towel, and a Rendle's cone with two sponges. To begin with the patient is lying down, if possible in the lateral position, at any rate with the head slightly turned to one side and only a little raised. The A.C.E. mixture is added from a drop bottle to the Skinner's mask or towel gradually, so that, beginning with one drop, by the end of about one minute the whole surface is made wet. The rapidity with which this can be accomplished depends mainly upon the character of the child's breathing. If the vapour causes inconvenient embarrassment of this, I proceed more gradually. If there be crying and free breathing the process is more rapid, the inhaler always being removed from the face for two full inspirations of air as soon as the crying ceases and respiration becomes quiet. Should the breathing be much interrupted, or held, it would indicate that the vapour is too strong. Much swallowing also indicates this. In that case the inhaler is removed an inch or two from the face without taking it completely away. The inhaler being visibly wet is kept so by frequent drops until respiration becomes fairly free. Rendle's mask is then rapidly substituted, containing a sponge upon which from half a drachm to two drachms of the A.C.E. mixture has just been poured. This vapour is stronger than the former, and the child will consequently strain and swallow a little in many instances; it may even wake up and cry again. The former precautions are now observed. If respiration be inefficient the Rendle's mask is

Hosted by Google

withdrawn half an inch or so from the face—never quite removed; but while respiration continues good in frequency and volume and not much interrupted by coughing, straining, or swallowing, the mask is kept closely applied. After perhaps from a minute and a quarter to a minute and a half from the change, respiration will again become fairly free and regular, without embarrassment or interference by the action of the reflexes, to which allusion has been made. When this happens I pour upon the sponge from one to three drachms of ether, according to the age and strength of the patient. This is done rapidly, the child only obtaining about one breath of air. The ether vapour wakes the child up again to some slight extent; swallowing and straining during inspiration probably reappear; but after a very little time, twenty or thirty seconds usually, the child becomes able to breathe the vapour as if it were ordinary air. When this sign occurs I pour upon a fresh, dry sponge, kept by my side, from two to three or even four drachms of ether. This sponge is then substituted for the sponge in use, and from that time onward the child only receives pure ether vapour. It is possible, if the vapour be very strong, that the child may be again partially awakened; but in a very little time—from ten to twenty breaths—respiration again becomes free and regular, and the child will then be ready for any operation. Nearly every child can be thus rendered ready for operation in four minutes or a few seconds over that time, and that without trouble, and with certain guides as to actions. The only guides to the changes of procedure are the symptoms connected with the respiration, but the time commonly taken is about one and a half minutes with the Skinner's mask, the same for the A.C.E. mixture upon the Rendle's mask, and thirty to forty-five seconds from the first addition of ether until the change to a pure ether vapour can be made. Having found that the child breathes the fairly strong vapour of pure ether without embarrassment, the operator is at once told that he may proceed. There is never under these circumstances any movement when the operation commences. Also the child is far enough removed from an overdose, as the variable or small pupil commonly present, often accompanied by slight nystagmus, testifies. Even weakly children require a continuous application of this strong vapour for from one or two minutes to produce stoppage of respiration from an overdose; and should this unfortunate event occur, even in weakly children, compression of the chest for a very few expirations will certainly restore the child to its former condition, the circulation, although the child may be pale when respiration ceases, being easily recoverable. But there is no need even for inexperienced administrators to produce this paralysis of respiration from an overdose of ether. The very fact that the child is able to breathe strong ether vapour leads one to intersperse breaths of air with the breaths of ether by removing the mask entirely from the face for one or two inspirations at a time. In this way, in the majority of cases, as soon as the operation has commenced the Rendle's mask is removed for eight or ten breaths. The vapour is withheld until some reflex change in respiration becomes excitable by its momentary reapplication. After this, unless the child is very strong, the application of the mask for about two-thirds of the time will be found sufficient to maintain the desired degree of narcosis. Indeed, in very feeble infants it is often only necessary to keep the mask applied for less than half the time. In a minute or two it is desirable to smell the mask, as the ether soon evaporates, and whenever the smell is not powerful a fresh supply is freely added. The quantity is not to be considered, for the patient's symptoms are the only guide, and the use of a strong vapour not only renders it unnecessary to keep the mask continually applied, but keeps one constantly informed as to the exact depth of anæsthesia present. During the use of any anæsthetic the only signs of the depth of narcosis are provided by the degrees to which, at any one moment, various reflex actions are annulled. With ether in children, when the reflexes upon which I rely are at the point of abolition, the vapour may always be withheld for some time without the slightest risk of any movement or of such interference with respiration as would make it difficult to continue the administration. As time proceeds still more evidence of reflex action on applying a fresh ether vapour may be allowed. After half an hour, for example, a weakly child may only require the vapour for one-fourth of the time. The gradual way in which children emerge from ether anæsthesia is one of the chief advantages and safeguards of the method, as it allows of a very nice gradation in the degree of narcosis produced.

A modification of the method, which I adopt in the case of very fractious children who scream and fight, is to dispense with the Skinner's mask. The Rendle's mask is used from the start, firmly held in position. This is the kindest way in such cases, as well as the easiest; but the precaution of removing the inhaler completely from the face for two or three breaths of pure air when the crying has ceased and the respiration is quite quiet must be rigidly observed. The after-effects of the method are not nearly so severe as might at first sight be imagined. Out-patients are usually sick three or four times in the first ten minutes after the discontinuance of the administration; they then sleep for a variable time, usually awake crying, and go off to sleep again. Prolonged crying is rare, so is prolonged sickness. With in-patients, even after operations lasting as long as an hour, vomiting is rarely observed for more than an hour or so after the administration. The occurrence of lung trouble after ether in children I believe to be almost absolutely preventable. In some hundreds of cases anæsthetised by students in the out-patient department by the method described, cases often lasting half an hour, inquiries were made as to the occurrence of cough and other troubles when they came to be dressed subsequently. Many of these patients were brought by their mothers in cold weather from considerable distances. We always kept them warm for an hour or two after the administration, especially in winter; but they then had to be taken home. Under such unfavourable conditions I could only hear of one case of bronchitis, and that was discounted by the fact that the child had a cold previously. With in-patients and in private, after a considerable experience of ether in children, I entirely agree with Mr. Braine that the risk of bronchial trouble is to be completely disregarded if the child be kept in a thoroughly warm room for some hours after the operation.

The dangers of the method, so far as can be judged after an experience of nearly 800 cases—the anæsthetic in many of them given by students—practically resolve themselves into the administration of an overdose. This contrasts strongly with the numerous ways in which dangerous symptoms may arise under chloroform. The symptoms of an overdose would be that the child, having been previously able to breathe a strong ether vapour, breathes probably in a more feeble manner two or three times, and then, more or less suddenly, ceases to breathe altogether. At the same time it becomes gradually pale and the pupil becomes widely dilated and fixed. It has been my lot to observe as many as three cases of this kind. The first case was that of a rather puny infant about to be operated upon for hare-lip. Wishing to do with as little chloroform afterwards as possible I instructed the student to press the ether after he had attained the point at which I have said any operation may begin. The child was breathing a strong vapour for perhaps one minute after this point, and then, while the surgeon was looking at the lips before making the incision, the inhaler having been removed, the child's breathing became shallow and soon ceased, and it became pale. The incision was now made and apparently caused the re-commencement of breathing, for that and the colour returned simultaneously within a few seconds after the incision. No other treatment was used and no further trouble arose. The second case arose through carelessness. I left a student giving the anæsthetic while I went to wash my hands at the other end of the room, where, however, I could hear the child's breathing. It was a pale baby aged seven months and a circumcision was proceeding. In a little time I no longer heard the breathing, and I walked to the table and remarked that the child had ceased to breathe while the student was still holding the inhaler over the face. This was at once removed, and I compressed the chest from the front with my two hands some eight or ten times, when respiration recommenced, and no further treatment was necessary. In this case, also, there was dilated pupil and pallor, which at once became a fair colour as soon as the breathing was re-established. In the third case, a child aged three years with a large tumour of the forehead, knowing that during the operation I would perhaps be hampered by being in the operator's way, I was pressing the ether after the child had lost all reflexes, the pupil not being very large. I was running a risk knowingly, and had just remarked to the onlookers that the breathing would become shallow if the vapour were pressed for too long a time. The breathing died away in a long-continued expiration without warning, and the child became rather pale with dilated pupils. With a

Hosted by Google

little artificial help to respiration he rapidly recovered, and his behaviour during a long operation was normal. In neither of these three cases did I feel any anxiety for the ultimate result; also, in all three cases the symptoms might have been prevented.

The advantages over chloroform of the method advocated are, I think, the shorter period of induction of anæsthesia, the greater certainty of the administrator's knowledge of the depth of narcosis, the freedom from movement which can be invariably attained during the operation, and—most important of all—the entire absence of dangerous symptoms, provided that one is only sufficiently observant to avoid an overdose, in reality an easy matter. In the following brief abstracts of a few of the cases, of which full notes were taken to illustrate the method, the time counts from the commencement of the inhalation.

CASE 2.—The patient was a baby aged four weeks, in fair condition. The operation to be performed was for extreme degree of cleft palate. A.C.E. mixture was commenced by the drop method; there were both straining and swallowing. At two minutes Rendle's mask was substituted with one drachm of A.C.E. mixture on sponge; straining and swallowing were present; the pupils 1 mm. At three minutes one and a half drachms of ether were added to the sponge; the patient was still straining. At four minutes a fresh sponge was substituted containing two drachms of ether. There was very slight alteration in the rhythm of breathing, the child relaxed, and therefore was ready. But as ether must be stopped when operation begins, it was continued for three minutes longer, the mask being removed about every fourth breath for one full inspiration of air. At seven minutes respiration was moist, regular, and free; the pupils were from 1½ mm. to 2 mm., and the globes were fixed. Mr. Lane's gag was inserted and operation begun. No more anæsthetic was given till eight minutes thirty seconds, when very slight movement in one hand was observed. From this time a little chloroform was given with Junker's inhaler. Nothing of note occurred until administration ceased at thirty-five minutes thirty seconds. The patient was put back to bed at forty-eight minutes, with good colour and pulse. There was no after sickness.

CASE 4.—This patient was aged three and a half years and weakly looking. The operation to be performed was to wrench a stiff ankle with a large wrench. A.C.E. mixture was administered by the drop method on a towel; there were two or three slight cries at first. At one minute thirty seconds Rendle's mask was substituted with half a drachm of A.C.E. mixture; the patient was quiet; respiration was regular. At two minutes forty seconds two drachms of ether were added. At three minutes thirty seconds fresh sponge with two drachms of ether; there was slight straining, culminating in one or two slight coughs at four minutes. The cough soon stopped; the pupils were 3½ mm.; the patient relaxed, and at four minutes ten seconds the operation began. Respiration was regular, but inspiration became crowing, and the wrenching was very severe. There was no other change. Up till six minutes thirty seconds the patient was breathing vapour for about two-thirds of the time; then operation over and administration ceased. From seven minutes thirty seconds to nine minutes thirty seconds there were one or two coughs and an occasional swallow. From eleven minutes thirty seconds to twelve minutes a little mucus was coughed up; then quiet sleep lasting till I left at fourteen minutes.

CASE 8.—This patient was aged nine years and well nourished. The operation was erasion of the knee. A.C.E. mixture was administered by a Skinner's inhaler, the patient resisting. At thirty seconds there was quiet breathing, with an occasional swallow. At one minute thirty seconds Rendle's mask with two drachms of the A.C.E. mixture was substituted. There was slight movement of the head and attempts to remove the mask. At two minutes thirty seconds the patient was quiet, but respiration was interrupted by frequent swallowing. At three minutes fifteen seconds two drachms of ether were added to the sponge; breathing was held, so the mask was raised occasionally a little distance from the face. At four minutes respiration was free; a fresh sponge was applied with four drachms of ether; respiration was fairly free, but frequent swallowing had returned. At four minutes thirty seconds the patient was quite flaccid; there was a strong lid reflex, the pupils being 5 mm.; the globes were moving; there was inspiratory stridor in breathing in response to the scrubbing, application of tourniquet, &c., then proceeding. At five minutes there was no lid reflex, the pupils were from 3½ to 4 mm., respiration was regular, but there was an occasional interruption in expiration. At seven minutes the mask had been kept almost constantly applied, and respiration was free, but the lid reflex had returned. The child was rather old for this method. Two drachms of ether were added, although the sponge was fairly wet. This vapour was breathed without difficulty, therefore the patient was enough under. At eight minutes the pupils were 3½ mm. with strong lid reflex. At ten minutes fifteen seconds there was one slight cough. Three drachms of ether were added, causing slight holding of the breath, which reflex was soon overcome. He had been quite flaccid the whole time. At twelve minutes the pupils were from 2 to 2½ mm., with no lid reflex. From fourteen minutes a strong vapour was given for two-thirds of the time. The pupil was kept small and respiration regular, with corneal reflex present. At twenty minutes sewing up was going on. At twenty-five minutes one drachm of ether was added, which caused slight stridor, the splint being applied. At twenty-seven minutes administration was stopped. At thirty-four minutes there were cough and retching. At thirty-four minutes thirty seconds the patient was put back to bed and vomited half an ounce of yellow mucus. Two hours later there had been no further sickness; he was sleeping; the pulse was 108; the respiration was shallow and regular. An hour later he was restless and crying for a short time. There were no further after-effects.

In summarising the sphere of usefulness of the method, I have no wish to deny that ether preceded by gas must still be considered the best anæsthetic for most children above the age of five or six years, when the anæsthetist is accustomed to its use. But the particular means that I have described is indicated alike in children for whom gas and ether is undesirable, and for routine use in children of all ages by those whose experience is not large. The absence of cyanosis and of undue congestion of the mucous membranes render this method peculiarly suitable for post-nasal cases where much obstruction exists, even up to twelve or fourteen years of age. In such cases the patient is allowed to breathe the ether vapour for two or three minutes, with occasional breaths of air, after he can first respire it freely. When a child is first able to do this the pupil is often of medium size, but as the inhalation continues it almost invariably becomes small. This is a useful guide in such cases, for one can then count upon three to five minutes of perfect anæsthesia and relaxation. Chloroform from a Junker's apparatus can always be resorted to at the end of this time if the operation is not finished. The youngest child in whom I have used the method was a few hours old, the operation for imperforate anus being somewhat prolonged, and the method proving all that could be wished.

Cavendish-place, W.

VAGINAL DOUCHING.

BY ARTHUR E. GILES, M.D., B.SC., M.R.C.P. LOND., F.R.C.S. EDIN.

ASSISTANT SURGEON, CHELSEA HOSPITAL FOR WOMEN.

VAGINAL douching has become such a universal practice, both in the hands of the public and under the supervision of medical men and nurses, that it may be well to review briefly some of the circumstances when it is required, and the most suitable solutions under varying conditions. At the outset it is necessary to raise a protest against unnecessary and too frequent douching. The researches of Winter, Döderlein, and others have shown that the vagina is normally inhabited by a benign bacillus, to which, through the formation of lactic acid, the acidity of the vaginal secretion is due, and the special *rôle* of which appears to be to antagonise and disarm of virulence any pathogenic organisms that may enter the canal. Frequent douching of the normal vagina, especially with soapy and other alkaline solutions, tends to hinder or arrest this beneficent action and to destroy the guardian bacillus. Hence, under the circumstances, morbid conditions are provoked rather than prevented. The same argument applies to the practice of giving a vaginal douche before or during labour, for when this is normal the uterine and vaginal secretions, followed by the rush of liquor amnii, tend to sweep the passages in the most effective way—namely,

Hosted by Google

from within outwards. Secondly, it is necessary to protest against a long-continued use of very hot douches, whether in health or otherwise. Frequently, in inflammatory and other conditions of the pelvic organs, the medical attendant orders douches "as hot as they can be borne." These have their place, and an important one, for their effect in relieving pain and pelvic congestion is often most marked; but this is provided they be used only as a temporary measure; not infrequently no later directions are given, with the result that patients continue these hot irrigations, perhaps twice a day, for months, and the means intended for cure become instrumental in prolonging and emphasising the complaint, by inducing chronic pelvic congestion with its consequent leucorrhœa. The remedy is simple—namely, that patients should be instructed to regard a hot douche as a temporary expedient, to be replaced as symptoms improve by tepid, cool, and even cold irrigations.

Indications for vaginal douching.—The use of a douche for purposes of comfort and cleanliness must be left in large measure to the discretion of patients, but they should be warned of the harm that may result from its too frequent use, as stated above. Therapeutically, the douche is indicated in three sets of conditions: (1) after labour; (2) after vaginal operations; and (3) in the treatment of inflammatory conditions of the vagina, uterus, and appendages. 1. After labour. When the labcur has been normal, with little or no intervention on the part of the attendant, and when the puerperium is also normal, it is open to question whether any form of douche should be used. In skilled hands no harm can result, and in lying-in institutions it is probably an advisable routine procedure; otherwise it is probably better omitted. In cases of post-partum uterine atony or hæmorrhage a hot douche is indicated, and when there is reason to fear septic developments a course of douching with mild antiseptics is desirable. In actual septic conditions one or repeated injections of stronger antiseptics may be required. 2. After vaginal operations. Here it is usually necessary to resort to vaginal douches for one or several weeks, either to keep the passages clear of blood, which would tend to decompose and so hinder the healing of wounds, or because there has been much manipulative interference. An aseptic or mild antiseptic solution generally suffices; at times, in septic conditions, a strong antiseptic is needed. 3. In inflammatory conditions. In these cases the douching is generally performed, not by the medical attendant or nurse as in the previous conditions, but by the patient herself or a lay friend. Hence more discrimination is required in prescribing potent solutions. Usually a bland solution is all that is necessary; in a few cases, as in gonorrhœa, some stronger antiseptic may be temporarily required.

The choice of a solution.—The fluids to be used for vaginal douching fall into three categories—(1) neutral or aseptic; (2) mild antiseptic; and (3) powerful antiseptic. 1. Neutral or aseptic solutions. Of these, the first is plain or sterilised water. For the relief of pelvic pain and congestion this answers perfectly. If a more astringent solution be required we may use alum, 1 to 2 drachms to the pint; acetate of lead, 1 ounce to the pint; chloride of lead, saturated solution; and permanganate of potash (Condy's fluid) in weak solutions. This is one of the most generally convenient on account of its portability and ready solubility. 2. Mild antiseptic solutions. Among these we may mention: boracic acid or borax, 2 drachms to the pint; sulpho-carbolate of zinc, 2 to 3 drachms to the pint; carbolic acid, 1 in 80 to 1 in 40; tincture of iodine, 1 drachm to the pint; Condy's fluid, 2 drachms to the pint; creosol, 1 in 250; lysol, 1 in 250; corrosive sublimate or the biniodide of mercury, 1 in 5000; or chinosol, 1 in 8000. Of these, boracic acid, sulpho-carbolate of zinc, and Condy's fluid are perhaps the favourites when prescribing a douche to be used by the patient. Chinosol is a comparatively new comer, but answers very well. I shall discuss it further among the stronger antiseptics. Carbolic acid and iodine are useful for hospital administration. The poisonous character of corrosive sublimate is a contra-indication to its indiscriminate use. For milder purposes other things answer as well, and in stronger solutions it should not be used except by the medical attendant. Lysol has the disadvantage of not being readily portable. 3. Powerful antiseptics. These are required after operations, and in obstetric practice, under septic conditions, and in the treatment of gonorrhœa and of septic conditions of the vagina and uterus. The most important are: carbolic acid, 1 in 40 to 1 in 20; iodine liniment, 1 to 2 drachms to the pint; corrosive sublimate, 1 in 1000 to 1 in 4000; and chinosol, 1 in 1000 to 1 in 8000. Of the first three we need not speak in detail, as their merits and demerits are well known. The desideratum is a material that shall be portable, readily soluble, non-toxic, and, at the same time, a powerful antiseptic. From this point of view a few words may be said about chinosol, which answers these requirements, and which, being a comparatively new drug, may possibly not be familiar to practitioners in this country, though used a good deal on the Continent. (For a recent account of bacteriological experiments I may refer to an article by Bonnema in the *Therapeutische Monatsschrift* for December, 1896.) It is a light-yellow powder which belongs to the quinoline group, and is readily soluble in all proportions of water. It is non-poisonous, and for this reason it is specially suitable for use by patients themselves and for douching after childbirth. Being put up in tablets, it is as convenient for carrying about as corrosive sublimate, and its antiseptic action appears to be considerable, being at least equal to that of corrosive sublimate. Where albuminous fluids are concerned, chinosol appears to be superior to the sublimate, inasmuch as it does not coagulate albumin; corrosive sublimate, on the other hand, forms an insoluble albuminate of mercury, whereby the antiseptic action is interfered with. Chinosol resembles iodoform in appearance; and this leads me to remark that if intended to be used in dressings or on tampons, as a substitute for iodoform, the chinosol powder requires to be diluted with boracic acid in the proportion of 1 part of chinosol to 5 or 10 parts of boracic acid.

When strong antiseptic solutions are required for vaginal douching, corrosive sublimate, carbolic acid, and iodine should be used only by the medical attendant; chinosol, for the reasons above stated, may safely be ordered for use by the patients themselves.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON "NEUROTIC" SYMPTOMS OF URIC-ACIDÆMIA IN THE YOUNG.

BY DAVID DRUMMOND, M.A., M.D. DUB., D.C.L. DURH.,
SENIOR PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE, ETC.

I WISH in the following short communication to call attention to a special group of symptoms, chiefly nervous and affecting the young of both sexes, which would seem to depend upon uricacidæmia. At first I considered neurotic or hysterical disturbance of function a sufficient explanation of these cases and treated my patients from this point of view, but with unsatisfactory results. My attention was called to the uric acid factor in connexion with the case of a young person in whom the symptoms in question developed, in the opinion of his friends, in consequence of the consumption of an excessive quantity of butcher's meat. This patient was put upon a milk diet and made a speedy recovery, but relapsed when restraint was removed and he was once more allowed to consult his own tastes. This led to an analysis of the urine in subsequent cases, with the result that the uric acid was found to be greatly in excess of the normal amount, and that even when the patients' diet was properly regulated. The symptoms are usually insidious in their origin and develop slowly, but in some cases a comparatively trifling indisposition has in a few days been transformed into a somewhat alarming illness. Headache is generally complained of from the beginning, and the chief characteristics are its persistency and its preference for the vertical and frontal regions. The appetite fails, and there is constipation along with other digestive disturbances, whilst anæmia and loss of flesh give the patient the appearance of illness. The temperature of the body is generally low, and in one case a night and morning observation, extending over three weeks, furnished a line that did not once reach the

Hosted by Google

normal point. The heart is peculiar and varies much in rate; at times it is rapid, but more often slow; indeed, this (slow pulse) is one of the most striking features of the complaint and will serve to arrest attention in a case that might readily be passed by with the diagnosis of simple dyspepsia, for it is not uncommon to find the pulse-rate 45 or 50 in the minute, which is all the more remarkable in face of the fact that the patient's manner is nervous. The pulse tension is raised, though it is seldom very high. The hands and feet are generally cold, and the fingers are white at times and possibly suggestive of Raynaud's disease. In some cases sudden attacks of giddiness occur which are difficult to distinguish from slight epileptiform seizures. The knee-jerk, as a rule, is distinctly lessened and may be absent, and a peculiar sluggish habit of mind and body may be noticeable along with other character traits foreign to the patient. In young women the menstrual functions are often in abeyance for months at a time.

The following case is fairly illustrative. A girl, aged sixteen years, experienced an illness of six months' duration which commenced with loss of appetite, constant headache, and constipation. She was taken from school and coaxed to eat considerably beyond her inclination, chiefly meat extracts and animal broths, but without improvement, as she grew weaker and lost flesh, and suffered from sleeplessness and a feeling of prostration in the morning. On examination the patient was found to be thin; she had lost half a stone in weight. The face was pale and muddy and the tongue furred and flabby. She was constipated, had constant headache limited to the frontal region, and was sleepless during the early part of the night. The pulse was rapid, over 100, and the tension high; the heart apex was prominent and a little to the left of the normal position. The knee-jerk was practically absent. The urine contained a trace of albumin; the specific gravity was 1030 and the amount of uric acid was 0·106 per cent. The total amount of uric acid excreted in twenty-four hours was 25 gr., or upwards of three times the normal amount.

In another case, that of a girl, aged fifteen years, the illness had lasted twelve months before she came under my observation. Loss of the knee-jerk, slow pulse (averaging 60 in the minute), constant headache, and dyspepsia were the most striking symptoms. In this case 13·8 gr. of uric acid were passed daily, about 0·061 per cent., or nearly double the normal amount.

My note-books contain a number of similar records which might be adduced, were it necessary, to illustrate further the connexion between uric acid and impairment of function in young people amounting to disease. The difficulty seems to lie in diagnosing between the hysterical or neurotic abeyance of function and that depending upon uricacidæmia, but in typical cases the slow pulse and the loss of the knee-jerk will point clearly towards the latter. I may mention that dietetic restrictions have produced excellent results in the majority of these cases. I am indebted to Dr. Robert Bolam for the analyses of the urine.

Newcastle-on-Tyne.

DELAYED DESCENSUS TESTICULORUM WITH SYMPTOMS OF INGUINAL INCARCERATION.

BY H. OPPENHEIMER, M.D. HEIDELB., M.R.C.P. LOND.

ON March 26th I was sent for to see a boy, five years of age, who had been quite well till two days previously, when, without any apparent cause, he was suddenly taken ill with violent vomiting, which had persisted and prevented his keeping down even the smallest amount of food. All this time he had been in a dazed condition; the bowels had not acted since the morning of the 24th. When I first saw the patient he appeared to be in a semi-conscious state from which he was easily roused so as to answer any question addressed to him, but he fell back into his dreamy condition immediately after having done so. The lips and finger nails were livid. The temperature was 101·2° F., and the pulse at the wrist was 125, feeble, and intermittent; but auscultation proved that the irregularity was apparent rather than real, the heart's action being so feeble that not every pulse-wave reached the wrist. On examination I found that both sides of the scrotum were empty, and in the left inguinal region I detected a tender swelling about the size of a smal pigeon's egg which was dull on percussion and resistant to the touch. Both inguinal rings were open; the left inguinal canal contained a hard tumour corresponding with the external swelling, while the right one was empty. I ordered an ice-bag to be applied locally, ice to be sucked, and sips of iced milk to be taken, and being doubtful as to whether there was not a strangulated bowel behind the enlarged testis I prescribed small doses of laudanum at frequent intervals. The next morning I was informed that the patient was decidedly better and that he had not been sick during the previous twenty-four hours. On inspection, however, I found that the cyanosis had deepened and spread; the heart was even weaker than it had been the day before, and locally there was very little change. I ordered brandy to be given in large doses and three leeches to be applied over the tumour. Free bleeding having taken place the size of the tumour diminished considerably. But now I discovered in the right inguinal canal a small mass presenting all the characters of a normal testis. Under appropriate treatment the orchitis rapidly disappeared, and by April 11th the patient had completely recovered and both testes lay outside the inguinal rings.

No doubt the above case was one of late descensus; the left testis had become strangulated during its passage through the inguinal canal, while the right one apparently descended without giving rise to any symptoms. But what is to my mind a most striking feature in this case is the peculiar bilateral synchronism of a fœtal process in extra-uterine life.

Crossfield-road, Belsize-park, N.W.

A FATAL CASE OF TETANUS ARISING FROM INJURY TO THE LEFT THUMB.

BY W. GORDON, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.,
HOUSE SURGEON TO THE SALISBURY INFIRMARY.

A MARRIED woman, aged forty-two years, fell on April 1st on the stalk of a chrysanthemum from which the flower had been cut; a piece of the stalk entered the ball of the left thumb. She poulticed the hand, not being aware of the presence of the splinter. On the 6th she was taken very ill, with pain in the back of the neck and shoulders, and she was at once sent to the Salisbury Infirmary, where she was admitted about eight o'clock on the 7th suffering from tetanus, convulsions occurring hourly and getting more frequent after admission. An abscess was pointing at the back of the left thumb. This was opened under chloroform and there was removed a large splinter, evidently part of a stalk of a plant. It was an inch long and about a quarter of an inch broad, with jagged edges. The abscess cavity was wiped out with strong carbolic acid and fomentations were applied. Nutrient enemata were given every four hours, together with large doses of chloral and bromide. Anti-tetanic serum was telegraphed for and arrived from London within three hours, but she was dying on its arrival. The convulsions, which had quieted under the chloroform, became more frequent, and she died about four o'clock in the afternoon. She was in bad health at the time of the injury. An inquest was held, a verdict of "Accidental death" being returned.

Salisbury.

DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY.—The annual meeting of the Devonshire Hospital and Buxton Bath Charity was held at the hospital on May 1st, Dr. Robertson being in the chair. The report showed that during the year ended April 30th there were 2770 in-patients under treatment, of whom 2472 were discharged as "improved," 6 died, and 172 remained on the books on April 30th. There were also 210 out-patients received during the year, of whom 161 were "improved." Of the 2770 cases 2184 were classed as rheumatism, arthritis, and gout; 179 were classed as diseases of the nervous system; and 850 suffered from heart disease connected with rheumatism and other morbid conditions. In the course of his address the chairman said that the effect of the Buxton water when used as baths is conditional upon its absorption through the surface of the body, and that the baths of the natural temperature are far more reliable than those which have been raised to higher degrees of warmth.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

A CASE OF RIGHT OVARIAN HERNIA WITH TWISTED PEDICLE; OPERATION; RECOVERY.

(Under the care of Mr. JOHN H. MORGAN)

THE persistence of the canal of Nuck, the great mobility of the ovary, and its comparatively high position in young children, sufficiently account for the fact that the presence of an ovary in a hernia is decidedly more frequent during the first twelve months than in the whole of the rest of life. The following case, however, is chiefly noteworthy from the partial strangulation from torsion which the herniated ovary had undergone. The condition is very rare and undoubtedly difficult to diagnose. We are indebted for the notes of the case to Mr. G. Templeton, surgical registrar.

An infant, aged eight months, was admitted to the hospital on March 9th, 1897, with a lump in the right groin. There was no history of hereditable disease, but it was of interest to note that a brother had died from strangulated hernia. The infant had always been delicate, and ever since she was four days old a small swelling had been observed in the right groin. Four days before admission this swelling underwent great increase in size, the skin over it became red, and the parts appeared to be very painful, the child screaming constantly and drawing up the right leg. She was convulsed on two occasions, but had not vomited, and the bowels were quite regular. A medical man was consulted, who advised removal to the hospital. On admission the child appeared to be very happy and peculiarly free from symptoms. The temperature was normal. On the right side of the upper part of the mons Veneris, extending over the right external abdominal ring, there was a rounded semi-elastic, non-fluctuating swelling, which was not altered in size when the child cried. On attempting to elicit fluctuation pain was produced, and very faint pitting of the skin could be made out on pressure. The child was very fat, but on further manipulation an indistinct, rounded, irreducible body, about the size of a cherry, could be felt and could be freely moved about, having, as it seemed, no connexion with the interior of the abdomen. The bowels had acted naturally and there was no sickness. She remained in the same condition until the 12th, when Mr. Morgan decided to operate, and having made an oblique incision over the swelling, he exposed a thin-walled sac in which some dark fluid was seen to be contained. A small incision through this membrane allowed the escape of about one drachm of blood-stained fluid, leaving exposed a smooth, rounded, plum-coloured body about the size and shape of a small damson. Attached to the upper end of this, which on closer inspection proved to be the ovary, was a slender pedicle twisted upon itself to the extent of two and a half turns. This stalk was found to consist of the right Fallopian tube and the broad ligament, and upon pulling them further outwards the fundus of the uterus entered the wound. The portion of the twisted pedicle, almost to its attachment to the uterus, was in a congested condition similar to that of the ovary. A fine silk ligature was passed round the pedicle beyond the congested part and tied, and the ovary and pedicle were cut off, and the uterus was dropped back into the abdomen. A suture was passed through the external abdominal ring and tied, and the surface wound was closed with a continuous horse-hair suture. The child recovered without a bad symptom and was discharged with the wound perfectly healed on March 24th.

Remarks by Mr. MORGAN.—Two cases almost identical with the above have been recorded during the past twelve months, with the variation that in both instances the condition had produced vomiting, thus giving rise to a closer analogy to a strangulated hernia of the intestine. In both cases the onset and symptoms, with the addition of vomiting, were similar to those in the case above described. The first was related by Mr. Lockwood as occurring in a child aged six months, and the second by Mr. Owen[1] in a child aged eleven weeks Both children recovered. A further resemblance is found to cases of testis retained in the inguinal canal where the spermatic cord is found to be twisted.

NORTH DEVON INFIRMARY, BARNSTAPLE.

A CASE OF MALIGNANT PUSTULE TREATED BY INCISION AND APPLICATION OF CARBOLIC ACID.

(Under the care of Dr. MARK JACKSON.)

THE following case demonstrates well the liability of contracting anthrax to which all are subject who have to do with hides even if only occasionally. A case resembling in some respects Dr. Jackson's was brought before the Brighton and Sussex Medico-Chirurgical Society by Dr. Black;[2] the disease attacked a man a few days after he had been employed in carting hay from railway trucks in which some hides had been carried a short time previously. Anthrax is decidedly less rare than was thought at first, and excision is not so necessary as it was formerly considered to be, local antiseptic treatment having in part replaced it; but excision is still the most certain method of removing the materies morbi and should be adopted whenever the position of the pustule permits. Should, however, excision be impossible from any cause the careful and thorough application of suitable antiseptics locally after incision offers the best chance of effecting a cure. For the notes of this case we are indebted to Mr. F. Penny, house surgeon.

On the evening of Oct. 30th, 1895, a railway porter, aged thirty-two years, was admitted into the infirmary. The patient was then suffering from extensive swelling of the left side of the neck, he was very feverish, the temperature was 103° F., the pulse was 86, and he was otherwise ill. He was sent to bed and a purge of calomel and jalap was administered. During the week previously the patient had been loading some skins, some of which were "high," and also some wool and sheep. Of the skins, one came from the neighbouring kennels and others from Ilfracombe. On Oct. 26th the patient felt a pimple on the left side of the neck, and in the evening, while being shaved by a barber, the top was taken off. He felt no inconvenience on the day following, but on rising about 7.30 A.M. on the 28th his neck seemed to be somewhat stiff and was swollen, and a scab had formed at the site of the pimple. During the day he became worse and he consulted a local practitioner, and on the next day there being no improvement, he was advised to go to the infirmary. Dr. Jackson first saw the patient on the afternoon of the 30th, at about 4 P.M. There was then a hard œdematous swelling of the left side of the neck, extending above over the left ramus of the jaw, downwards to the clavicle, and anteriorly beyond the middle line of the neck. In the centre of the swelling was a small purple spot about three lines in diameter surrounded by three large bullæ of a yellowish-brown colour. The patient complained of some difficulty in swallowing, apparently due to the extensive œdema. The axillary glands were slightly enlarged. On palpating the swelling, it was found to be somewhat elastic, and fluctuation was thought to be felt. It was determined to make an incision, which was done under chloroform A director was used, as the line of incision lay parallel to the course of the carotid vessels, but was introduced only by considerable force, so great was the induration of the tissues. An incision from one and three-quarters to two inches long was made, and as no pus was discovered a pair of forceps was introduced into the deep tissues to make sure there was no accumulation of pus beneath the deep fascia. Only serum and a little blood came through the incision. During the same evening Mr. F. Penny examined microscopically the fluid taken from the bullæ, and well-marked specimens of the anthrax bacillus were easily seen. On the 31st, on Dr. Jackson's advice, in consequence of

finding the bacilli, Mr. Penny swabbed out the incised tissue thoroughly with pure carbolic acid, and dressed the wound with carbolic oil and poultices. On the previous night the patient had been restless; he had had little sleep, and was sick after a draught of chloral and bromide. There was a scarlet, erythematous rash on the neck and chest. The temperature was 105° and the pulse was 96. On Nov. 1st the patient had passed a very restless night; there was much pain at the back of the head; the tongue was dry in the centre; the erythema on the chest extended to the level of both nipples. Albumin was abundant in the urine. The pulse was steady and regular. More bullæ were present near to the site of the inoculation, but no bacilli were found in their contents. The swelling of the neck was not so extensive. Four ounces of brandy were given. The patient had a bad night, was restless and delirious—for which a draught of chloral and bromide was given—and he vomited and perspired freely. On the following day (the 2nd) the erythema was not so vivid, but extended three inches below the level of both nipples. The patient wandered at times, but could easily be roused to talk sense. On the 3rd the sore was drying up; there was a gangrenous black edge, three-sixteenths of an inch in width around the upper part of the incision; the swelling was less, more moveable, and less indurated. The albumin in the urine was less and he had a more comfortable night, although he wandered a little at times and perspired freely. On the 4th the tongue was moist. The pulse was steady, regular, and of good volume. There was only a trace of albumin in the urine. The patient slept a good deal, but appeared to be all right when awake. On and after the 6th the temperature did not exceed 99°, having gradually fallen since the last observation. Up to the 20th progress was continuous. The swelling at that time was about the size of a duck's egg; the incision looked healthy, but there was a black slough in the centre. This was dressed with iodoform and wool dressing. The albumin had cleared from the urine. Although the patient had lost about 7 lb. in weight and looked pallid he was still growing in strength daily, and had been up about a week. He ate and slept well.

Remarks by Dr. JACKSON.—Perhaps I may be allowed to call attention to one or two points of interest in this case. As regards the diagnosis I think there can scarcely be a doubt in anyone's mind after seeing the case or examining the slide showing the bacilli. It is true that specimens of blood and of serum from some of the vesicles were sent to the Local Government Board, and their officers reported that they did not find any anthrax bacilli in the specimens. I may state that these specimens were taken after the application of pure carbolic acid to the tissues as mentioned above. According to Erichsen, "the anthrax bacillus shows a marked predilection for the most superficial parts of the papillary layer of the cutis immediately beneath the rete Malpighii," and it is possible that to the early destruction of these organisms at the site of inoculation by the carbolic acid may be due the favourable termination of this case. Another point of interest is the patient's occupation. Most cases of malignant pustule have occurred amongst those trades dealing either in hides or skins of cattle, in certain classes of foreign wools, in manure stores, or amongst slaughterers of animals or constables having to dispose of the carcases of animals dead from anthrax, or, again, amongst those having to nurse cases of malignant pustule, as nurses and medical men, where they have been inoculated through the surgical dressings, &c. I find from an annotation in THE LANCET of July 28th, 1894, p. 207, that of 118 cases treated in London since 1873 the occupations were thus classified: Of 118 cases, 90 were engaged in skin and hide trades; 5 in slaughtering animals; 7 in persons engaged in the manipulation of horsehair or in the manufacture of brushes; and in 15 instances the source of contagion was unknown. I have not been able to find at present any case before mine of malignant pustule in a railway porter. Now it happens that on Oct. 25th and 26th certain hides passed through the Torrington Station, one of which came from the neighbouring kennels, where the flesh had been given to the hounds, and presumably was diseased, and others came from Ilfracombe. Locally it is well known that a very serious outbreak of anthrax occurred in the latter district early in the spring, and that a herd of cattle was practically destroyed in a few days. At the present time I have not been able to trace any direct connexion between these events, excepting that the patient was on duty and helped to load these skins when they passed through the Torrington station. Another point of practical interest is this. How long is it after inoculation of the poison before the symptoms supervene? I have just mentioned that in this case the date of inoculation was either Oct. 25th or 26th and that the patient complained of illness on the morning of the 28th, so that there was an interval of from two to three days. I have looked up other published cases and find in one that the time was indefinitely stated to have been a "few weeks." In another a constable was inoculated through a scratch of the hand on July 24th, 1893, and was dead by July 26th. In another case the man died on the fourth day after a slight abrasion of the arm. Mr. Pagan Lowe of Bath described a case in THE LANCET of Jan. 23rd, 1892, of a woman who had nursed her husband with malignant pustule and was attacked on the fourteenth day afterwards. In another remarkable instance where three men were exposed simultaneously to the same contagium one showed symptoms four days after inoculation, the second six days, and the third ten days. Of these three only the first died. The last point to which I would draw attention is the treatment in this case. Perhaps I ought to say this was not intentionally adopted in the first instance. In almost all published cases the greatest emphasis is laid on the duty of the surgeon to remove without delay the area of diseased skin at the site of inoculation. Erichsen is no less emphatic in the same direction. Of a series of fourteen cases treated by Mr. Davies-Colley at Guy's Hospital all were excised, but in eight cases external application of chloride of zinc was made in addition, of which two died; of the six remaining cases treatment by ipecacuanha, both locally and internally, was added, and of these none died. This latter treatment was advocated by Dr. Muskett in THE LANCET of 1888, p. 269, I have only discovered one case treated in the same manner as my own and this was in Victoria and is said to have been the first in that colony—here the case also recovered, but, it is added, "without constitutional symptoms" I have mentioned the statement by Erichsen and others that the special habitat of the anthrax bacillus in malignant pustle is in the superficial layers of the cutis, and it is perfectly reasonable therefore that the earlier these bacilli are removed by way of incision or destroyed by chemical agents the more probable is it that the disease may be confined to a merely local affection. But I may mention that, according to Dr. Sidney Martin, whose Goulstonian Lectures for 1895 dealt with this and other infective bacilli, the danger in this and other allied affections is the "presence of specific poisons in the system, the products of the primary infective agent." In the case of anthrax these poisons are of two classes—(1) certain albumoses, to which are due largely the fever and its concomitant symptoms, and (2) an alkaloid acting chiefly on the nervous system and responsible for the prostration and coma in fatal cases. It seems to me, therefore, that we have here the *rationale* of successful treatment by incision. The exudation from the tissues through the incised wound practically carries with it the poisons as well as the bacilli which may have accumulated in the tissues, whilst the application of pure carbolic acid or strong tincture of iodine would destroy what other bacilli may still be lurking behind. I may add also that the ipecacuanha treatment has been based on the destructive action of ipecacuanha on the anthrax bacilli as determined by experiments made by Mr. F. C Evans. I believe it will be admitted that the case here related was one of exceptional severity, as shown by the temperature, by the extent of the œdema, the albumin in the urine, and the delirium present, and I think the result as seen in this patient would encourage me to pursue the same line of treatment should any other case ever come under my care.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND. — The next general meeting of this association will be held at 11, Chandos-street, London, W., on Tuesday, May 18th, at 4 P.M., under the presidency of Dr. Julius Mickle. Dr. F. W. Mott, F.R.S., will read a paper on Some Points concerning the Degeneration of the Neuron, with a lantern demonstration. Dr. E. Goodall will describe an Exact Method for Recording Deformities of the Hard Palate. Dr. T. Seymour Tuke will contribute a medico-legal note on Stay of Action by application to a Judge of the High Court, under Section 330 of the Lunacy Act, 1890. The members will dine together after the meeting at the Café Royal, Regent-street, at 6 30 P.M.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Relations between Bodily Development, Nutrition, and Brain Conditions in their Pathological Aspects.

A MEETING of this society was held on April 27th, the President, Dr. HOWSHIP DICKINSON, being in the chair.

Dr. FRANCIS WARNER read a paper on the Relations between Bodily Development, Nutrition, and Brain Conditions in their Pathological Aspects. The purpose of the paper was to show, as the result of extended observation among children, that: 1. Points of abnormal development in the body are very common and have important signification. 2. Abnormal nerve signs, or points in balance and movement, have been defined; they are much associated with defective development as well as with the causes of mental dulness, and are of clinical importance. 3. There is a close empirical relation between (*a*) defective development of the body, (*b*) abnormal nerve signs, (*c*) low nutrition of the body and its tissues, and (*d*) mental dulness and backwardness. Some explanations of the relations among the classes of defect were offered. After referring to his paper on Postures of the Hand as Indications of the Condition of the Brain, read before the society in 1882, Dr. Warner said that in that investigation and a subsequent one he was enabled to examine between 1888 and 1894 100,000 children individually, in conjunction with other medical men, the results of which had been published in a report;[1] notes of 18,127 cases in some respect below normal were taken. After briefly describing the method of the statistical examination of facts four main classes of defect observed were described: (*a*) Defect in development in size, form, proportion of parts of the body, principally in cranium, palate, ears, and features, as well as more gross deformities; such signs were disproportions in ratios of growth. (*b*) Abnormal nerve signs in balance and action or reaction in movement and coördination as seen in the face and eyes, the upper extremities, the hands, digits, and balance of the body. (*c*) Low nutrition; cases pale, thin, or delicate. (*d*) Cases dull or backward mentally, as reported by the teachers. The developmental signs were disproportions in growth; the nerve signs were abnormal in the time of action or in the ratios of action among the nerve centres. Movements were classified as: 1. Uniformly repeated series of movements, the same parts moving in similar combinations and series of acts on successive occasions. Athetosis and athetoid movement of the frontal and corrugator muscles, with grinning, were types of this class. 2. Augmenting series of movements, the area of movement spreading from part to part. The expression of mental excitement and emotion, awaking from deep sleep to activity, the extra movements of fidgetiness, the march of the spasm in epilepsy, and convulsions afforded illustrations. 3. Diminishing series of movements, as seen when excitement subsided, as sleepiness came on, and as the convulsion subsided or chorea passed away. 4. Coördinated movements, such as were adapted in their relations in time and in quantity of action by the environment, and therefore in harmony with it. It was shown that in each class the character of the movement depended upon the attributes of time and quantity of action in nerve centres. The inference from the observed co-relation of development defect with abnormal nerve signs was that when proportional growth in body was abnormal, as a sequence of inheritance or otherwise, the nerve centres were commonly so built up that in subsequent action they did not work in the normal relations of time and quantity under the influence of the environment. It was shown that disproportion in growth and development of the body was commonly accompanied by a status of the tissues prone to atrophy under adverse circumstances. This was especially the case with girls, who were, therefore, liable to fall into permanent ill-health with neuroses. Incoördinated nerve action, such as fidgetiness, awkward habits, or chorea, commonly occured with a lowered status of nutrition, and suggested the hypothesis of a reversion of spontaneity in action, which was characteristic of the normal infant brain (microkinesis) Dr. Warner submitted the following propositions: 1. Disproportioned bodily development is very common; it is co-related with low nutrition of body and incoördinated brain action. The co-relation with low nutrition is highest with girls of all ages and is specially marked among children seven years of age and under; it is much lower at eleven years of age and over. The co-relation with nerve signs increases with age for girls, and less so with boys. Finally, the proportion of the developmental cases that have not acquired either low nutrition or nerve signs is highest for boys in the oldest group, while for girls it remains about the same in each age group. It seems that the environment is apt to produce more harm and less good in girls than in boys of imperfect development. 2. Incoördinated brain action is much associated with mal-development, and the presence of nerve signs is more co-related with the causes of mental dulness than are the signs of defective development. The co-relation of nerve signs with mal-development is highest for children seven years of age and under and lowest in the oldest group of cases; while the proportion of nerve cases that have nerve signs only without low nutrition is highest with the oldest group. The environment appears to favour the occurrence of simple cases of nerve incoördination and weakness, which in many instances might be removed by training; such signs are much associated with mental dulness. 3. Delicate children are in a large proportion of cases ill-developed in some part of the body. Among children without developmental defect there does not seem to be a larger number of delicate girls than boys; it is the girl who has some defect that is delicate, not all girls. Developmental cases tend to remain thin and delicate in all social classes, least so in resident institutions.

Dr. NORMAN MOORE said that he could not pretend to be fully acquainted with the methods of investigation adopted by Dr. Warner, but speaking as an outsider it seemed to him that there were some flaws in the argument. Everyone who worked much in the post-mortem room wished to find some law of correlation between defects of different parts of the body, but had to abandon the hope. It was only exceptionally, for instance, that abnormalities of other organs were found in cases of congenital disease of the heart, and he thought it by no means proved that there was any regular correlation between mental and structural defect. Antics and abnormal gestures might, as in the case of Dr. Johnson, be accompanied with mental qualities of an unusually high order. He did not think that a child should be put down as dull merely because he had difficulty with his lessons; the fault might lie with the teacher. Large ears, again, were not necessarily signs of mental defect, as they were often seen in those of high capacity. From post-mortem observations on such variable arrangements as the number and attachment of the cords of the mitral and tricuspid valves he could not confirm Dr. Warner's statement that variations were more common in males than in females. The "uniformly repeated series of movements" on which Dr. Warner laid such stress he should regard as merely habits, and as often associated with high as with defective mental development. It would be important to know what was the ultimate mental development of the children described as dull, as Johnson, Pope, and many others had been classed as dullards when young. He thought that there was an insufficient basis of observed facts to enable dogmatic conclusions to be drawn at present with regard to the painstaking investigations of Dr. Warner.

Dr. FLETCHER BEACH expressed his general agreement with the criticisms of Dr. Norman Moore. The abnormal mental development could not be ascertained by any simple test, but by the weighing of a host of separate observations which were of very unequal value, but taken together of great importance. Nerve signs alone were insufficient to enable one to form a dogmatic opinion. Many of these signs were prominent in children with marked neurotic heredity, but who were bright and quick. Before accurate conclusions could be drawn it would be necessary to follow up the cases and also to extend the scope of the inquiry to other parts of the country besides London, and especially to agricultural districts, where the children were presumably less highly nervous.

Dr. SHUTTLEWORTH said that he could testify to the conscientious and accurate way in which Dr. Warner had

[1] Report on the Scientific Study of the Mental and Physical Conditions of Childhood, with particular reference to Children of Defective Constitution, and with Recommendations as to Education and Training, based on the Examination of 100,000 children, 1888-94. Published by the Committee, Parkes Museum, London, W.

Hosted by Google

conducted his observations, although he might not be able to follow him in all his conclusions. His experience had been chiefly among imbecile children, and there was no doubt that in them there was associated physical defect, both as regards weight and stature and also as regards the skin, viscera, and bony parts. The same arrestive cause was probably operative in both mental and physical conditions. Twenty-eight of the cases had a tuberculous family history, and the mortality was eight or ten times as great among imbeciles in asylums as in the outside population. Pope and Johnson could not be taken as healthy types. They illustrated Dryden's lines:—

"Great wits are sure to madness near allied,
And thin partitions do their bounds divide."

Dr. WARNER, in reply, said that in his paper he had purposely left out any consideration of the abnormal signs to mental states, but he might say that out of 1900 boys and 1000 girls who showed well-marked nerve signs 40 per cent. of the boys and 52 per cent. of the girls were found to be dull. He believed that anatomical defects were often associated with these abnormal mental cases, and mentioned one in which there was an abnormal arrangement of the cerebral convolutions, a congenital deficiency in the size of one eye, a defective septum ventriculorum, and a horseshoe kidney. It was only by the multiplication of observations of signs that it was possible to say that a person was abnormal. Uniform repetition of one set of movements was certainly more common in defective children, and it passed off when the mental condition was improved.

MEDICAL SOCIETY OF LONDON.

Election of Officers.—Exclusive Red Meat Treatment of Certain Cases of Gout.—Excision of Rectum.

THE annual general meeting of this society was held on May 10th, the President, Mr. REGINALD HARRISON, being in the chair.

The reports of the council and treasurer were adopted, and the following gentlemen were appointed to hold office during the ensuing year:—President: Dr. A. Ernest Sansom. Vice-presidents: Dr. Constantine Holman, Mr. A. Pearce Gould, Dr. J. Kingston Fowler, and Mr. John H. Morgan. Treasurer: Mr. David H. Goodsall. Librarian: Dr. William Henry Allchin. Honorary Secretaries: Dr. Robert Maguire and Mr. William H. Battle. Honorary Secretary for Foreign Correspondence: Mr. Alban H. G. Doran. Council: Dr. Theodore D. Acland, Dr. John Anderson, Dr. E. Clifford Beale, Dr. Frederick L. Benham, Dr. Robert L. Bowles, Dr. William Ewart, Mr. Reginald Harrison, Mr. Henry E. Juler, Dr. Norman Kerr, Mr. Charles B. Lockwood, Mr. Jonathan F. C. H. Macready, Dr. James W. J. Oswald, Mr. C. J. Rayley Owen, Dr. Amand Routh, Mr. Morton Smale, Dr. John C. Thorowgood, Mr. George R. Turner, Mr. W. Dakin Waterhouse, LL.D., Mr. Joseph White, and Mr. Arthur K. Willis.

The adjourned discussion of the paper by Mr. W. Armstrong on the value of an Exclusive Red Meat Diet in certain cases of Gout, was resumed by Dr. ARCHIBALD GARROD, who said that he had met with many cases of chronic rheumatic arthritis which had been treated in this way, in some instances with advantage, in most without result. It was really carrying to an extreme degree the plan of feeding up these patients, who were often harmed by a too restricted diet. Probably no single explanation would be adequate to account for the improvement in all the cases. Very few of the successful methods of treatment, such as the relief afforded by colchicum during the acute paroxysms, had yet been explained on scientific grounds It was obvious that there was a fundamental difference between the cases in which there was acute gouty arthritis with a deposit of urate of soda around and in the joint, and cases of chronic articular gout in which there was an alteration of the nutrition of the joint leading to extensive changes in its whole structure. In the case of uric acid calculi there was another process, the decomposition of the quadri-urate, the occurrence of which depended on many variable conditions, such as the amount of saline constituents in the urine, or even the amount of pigment. The line of treatment recommended by Mr. Armstrong was calculated to increase the amount of uric acid produced and was therefore unsuitable in cases in which there was any evidence of kidney disorder, which he thought was the rule, at any rate to a slight extent, in cases of gout. The improvement in many cases was probably due to the fact that many of the digestive organs obtained an almost complete rest, and the sudden change appeared often to be beneficial. In true gout he thought that the applicability of this mode of treatment was limited, and that it was by no means free from risk.—Dr. A. P. LUFF said that he had shown that there was no difference between the metabolism of animal proteids and that of vegetable proteids. Probably their different effects as articles of diet depended on the accompanying saline constituents. The mistaken idea that a meat diet caused the introduction of increased quantities of uric acid into the blood was responsible for the objection to meat as an article of diet for the gouty that many held. He believed that in healthy people uric acid was formed in the kidney only from urea and glycocin which came from the liver. In morbid states of the kidney, structural or functional, the uric acid was absorbed from the kidney, and it might be derived from the breaking down of nuclein in leucocythæmia. A person on animal diet excreted more urea, but not more uric acid than when he was taking purely vegetable diet. At the previous discussion Dr. Haig had abandoned his former contention that meat diet introduced uric acid into the blood, but said that xanthin, which he considered as physiologically equivalent, was so introduced. He appeared to rely on Haycraft's process for detecting this, but in 1891 Dr. Haig himself showed that Haycraft's method was unsuitable for detecting xanthin, and there was no proof that xanthin if introduced would contribute to the production of gout. He agreed with Dr. Garrod that there was almost always some renal disability in cases of gout, and that this plan of treatment could only be safely carried out in a few carefully selected cases.—Dr. P. J. FREYER said it was impossible to accuse a meat diet of being the cause of the deposit of uric acid in the face of the fact that the people most subject to manifestations of gout were the vegetarian inhabitants of North-West India.—Dr. R MAGUIRE said that the question was not one of chemistry, of diet, or of microbes, but of vitality. In the carnivorous serpent uric acid was passed practically in the form of a calculus; the graminivorous bird passed it in the form of urates, and the most highly evolved man in health passed it in solution in the urine. But when his vitality was lowered there was a process of devolution, and uric acid was deposited. The Hindoo was a man of very low vitality, and deposition of uric acid readily occurred even on a purely vegetable diet.—Mr. ARMSTRONG in reply, took exception to Dr. Haig's view that the meat acted only as a stimulant, or that its action was the same as that of the Carlsbad waters. The effect of these Mr. Armstrong believed to be due to increased elimination of uric acid by the kidneys and the skin. The influence of the nervous system in deranging the normal chemical processes in the body was a very potent one, and he had seen worry repeatedly produce a deposition of uric acid in a woman who never touched meat. He thought that much of the benefit was due to the sudden cleavage in the habits of diet. Several of his patients had previously suffered much from amylaceous dyspepsia. He wished to insist that this mode of treatment was not a panacea. The cases had to be carefully selected, and only about 3 per cent. proved to be suitable.

Mr. F. SWINFORD EDWARDS read a paper on Fourteen Consecutive Cases of Removal of High-lying Cancer of the Rectum by Kraske's Method. The object of the paper was to show that many cases of rectal cancer hitherto deemed beyond the reach of operation are by the sacro-coccygeal or coccygeal route quite capable of removal without undue risk to life, and that after the resection in certain cases rectorraphy may be successfully carried out, with restoration of the part. Cases were quoted in which patients were alive and well, with no signs of recurrence, after periods varying from one and a half to six years. Mr. Edwards thought that a preliminary colotomy was usually unnecessary, as it involves a waste of time and may prevent a rectal anastomosis by fixing the colon, and so make it impossible to pull down the upper rectum; and it is the more unnecessary since there is little liability to subsequent stricture after operations by this method. Besides, if patients have to submit to the formation of an artificial anus, they prefer to have it in the perineum, in the neighbourhood of the original outlet. Mr. Edwards considered that if a rectorraphy is to be successfully carried out the peritoneum and sub-peritoneal tissue should be freely incised to allow the upper rectum to be approximated to the lower. Out of fourteen cases

Hosted by Google

in which he had operated there had been only two deaths (the mortality on the Continent appears to vary from 18 to 34 per cent.). Recurrence occurred in two cases, in one in two years and in the other in four months. Ten are living and well, one of these after five years, two after nearly three years, one after nearly two years, three after one year, one after six months, and one after three months; one patient operated upon eighteen months ago has been lost sight of. Mr. Edwards anticipated that by attention to details and judicious selection of cases still better results would be obtained.—Dr. SNOW thought that, if possible, the removal of bone should be avoided. Mr. Edwards had reported one of the cases as one of scirrhus of the rectum, but it was doubtful if that form of cancer ever arose there.—Mr. BIDWELL said that the chance of complete cure was so considerable that probably patients would be willing to run the risk of a 20 per cent. mortality.—Mr. EDWARDS, in reply, said that Dr. Abraham, who examined the growth microscopically, reported that it was undoubtedly a scirrhus.

OBSTETRICAL SOCIETY OF LONDON.

Chronic Axial Rotation of an Ovarian Cyst.—Abdominal Pregnancy at Full Term; Operation at the Twelfth Month; Recovery.—Lantern Demonstrations.

A MEETING of this society was held on May 5th, the President, Dr. C. J. CULLINGWORTH, being in the chair.

Dr. THOMAS WILSON read a paper on a case of Chronic Axial Rotation of an Ovarian Cyst giving rise to Extreme Twisting of the Elongated Uterus. The patient was a multipara, aged fifty-five years, whose abdomen had been gradually increasing in size for four years; for two years there had been frequent attacks of pain and vomiting, many of which were caused by lifting a heavy invalid husband. By operation a tumour was removed after tapping, by tying and dividing a pedicle as thick as the thumb and two inches long. The tumour was a strangulated, multilocular glandular cyst of the left ovary, weighing about five pounds. To the lower part of the cyst were attached the fundus uteri and the right ovary, tube, and broad ligament, all strangulated. The cyst had a very broad and thick attachment to the left side of the uterus, and the latter organ had been twisted almost through in a direction from right to left. Both tubes were occluded and adherent, the right forming a distinct hydrosalpinx; the left was nine inches long. The patient made an excellent recovery and has continued well.—Dr. HORROCKS pointed out that in most cases of axial rotation there had been effort or exertion whilst in a bent position. He quoted a case where it occurred suddenly when a woman was pulling on a boot which was rather tight. He thought that great force must be exerted upon a tumour in the direction of axial rotation when an effort was made while the body was in a bent position.—Mr. DORAN was surprised to hear that in Dr. Wilson's three cases where the uterus was involved in the rotation the cyst was of the multilocular, glandular type. In twisting of the pedicle alone the tumour was dermoid in a considerable proportion of cases. Much remained to be learned about axial rotation. He had operated on patients where all the clinical symptoms pointed to twisted pedicle, yet nothing was found except soft parietal and, perhaps, omental adhesions. He had found the pedicle short and slightly twisted in cases where the patient had nothing to complain of except the presence of an abdominal tumour; on the other hand, he had found a long pedicle moderately twisted in cases where there were typical symptoms including severe pain.—Dr. WILSON replied.

Mr. JOHN W. TAYLOR then read a paper on a case illustrating the Treatment of (so-called) Abdominal Pregnancy at Full Term; Operation at the Twelfth Month; Recovery. He gave a detailed account of the previous history of the case and of the condition of the abdomen and pelvis at the time of examination. The patient believed that she became pregnant twelve months before the operation. She felt exactly as she had done in former pregnancies, but the movements of the child were unusually distinct and painful. Except for an attack of hæmatemesis the patient was up and about during the whole time. At no period was there any acute pain, sudden illness, or fainting. A description was given of the operation of abdominal section for the removal of the child and placenta. The placenta was of ordinary size and covered the pelvic inlet "like the lid of a saucepan incompletely closed," the edge of the placenta being exposed and free on the left side of the pelvis, but closely applied to the abdominal wall on the right side where the cord was situated. Its attachments were: (1) a thick band or rope of omentum, firmly attached to the upper or serous edge of the placenta on the left side; (2) several thin attachments or adhesions of small intestine and cæcum to the same surface; and (3) the deep pelvic attachments of the under-surface of the placenta. Mr. Taylor described his bloodless method of removing the placenta. The paper concluded with a short commentary on the origin, growth, and history of the case.—After remarks by Dr. LEA, Dr. HEYWOOD SMITH asked whether the medical man who first saw the case when labour pains came on had made any examination, as the condition might have been recognised and the child's life saved by an earlier operation.—Mr. DORAN thought this case seemed an argument in favour of postponing operation when ectopic gestation was advanced till some time after term. The removal, or the leaving behind, of a nine months' placenta was a more serious matter than the removal of the degenerate structure which represented it several months later. Operation seemed more urgent at term, however, in a class of cases, first distinguished by Freund, where continuous intestinal catarrh denoted the intimate attachment of the placenta to the intestine. This histological union involved immediate danger from sepsis as well as from hæmorrhage.—Remarks were also made by Mr. BLAND SUTTON, Dr. AMAND ROUTH, Dr. WILSON, and the PRESIDENT.—Mr. TAYLOR, in reply, said that the attachments of the placenta were very vascular and that the vessels could be felt pulsating before the forceps were applied. The main point, however, was, that as each vascular connexion was controlled before separation, the same operation might have been performed at any previous period of the pregnancy, and if the patient had come to the hospital at the time of the supposed labour, it might have been quite possible to save the life of the child as well as that of the mother. The collection of caseous masses found below the placenta was at the extreme lower pole of the pregnancy sac. This reached to the bottom of the pelvis on the right side, and the reflexion of the sac could be traced upwards from the floor of the pelvis along the broad ligament to the under surface of the placenta, and it was in this lower pocket of the sac that the caseous masses had accumulated. In reply to Mr. Doran, he would always prefer to operate at term, and under no circumstances would he purposely wait for the death of the child before opening the abdomen.

Mr. BLAND SUTTON gave a lantern demonstration on Myoma of the Cervix Uteri.

Mr. TARGETT gave a lantern demonstration on Accessory Adrenal Bodies in the Broad Ligaments.

OPHTHALMOLOGICAL SOCIETY.

New Method of Mounting Museum Specimens.—Unusual (congenital) Defect of Centre of the Cornea.—Three Specimens of Detachment of the Retina.—Sarcoma of the Iris.—Symmetrical Disease of the Macula.—Obstruction of the Cavernous Sinus.—Translucency of the Cornea after application of the Galvano-cautery.—Congenital Absence of the Puncta Lacrymalia.—Proptosis occurring on Stooping or Compressing the Jugular Vein.—New Growth in the Yellow Spot Region.—Retinitis Punctata Albescens.

A CLINICAL evening of this society was held on May 6th, Mr. E. NETTLESHIP, the President, being in the chair.

Mr. PRIESTLEY SMITH showed specimens illustrating a New Method of Mounting Eyes in Formol, which could be completed in forty-eight hours. The preparations were permanent and exhibited clearer definition than those preserved in glycerine jelly.

Mr. HARTRIDGE showed a patient who exhibited a remarkable Congenital Deformity of the Cornea, whereby the central portion was hypermetropic to the extent of 6 D, whereas the periphery was emmetropic. There was a slight nebula.

Mr. ERNEST CLARKE exhibited three mounted specimens of Detachment of the Retina in Different Stages. In the first there was no inflammatory thickening; in the two others there had been inflammation, and in one of these there had

Hosted by Google

been in addition the formation of cysts in the detached portion.

Mr. C. DEVEREUX MARSHALL described and exhibited sections of a case of Sarcoma of the Iris. There was a solid unpigmented mass occupying the position of the lens and growing from the posterior surface of the iris; it proved microscopically to be a small round- and spindle-celled sarcoma. Mr. Lawford, who removed the globe, said the eye was glaucomatous. There was no anterior chamber, and a white mass occupied the centre of the pupil simulating opaque swollen lens substance. It was while operating for the relief of this supposed condition that the real nature of the case became apparent and the eye was excised.

Dr. BATTEN brought forward cases illustrating Symmetrical Disease of the Macular Region in two brothers due to hereditary syphilis and arising at the age of fourteen years. Vision was greatly reduced in both instances. Failure of sight had been gradual and one other member of the family—a girl—was unaffected.—Mr. JESSOP mentioned a somewhat similar case in which vision failed at the age of twenty-one years; it began with œdema at the macula, followed by pigmentary change. Disturbance of vision had been sudden, first in the left and then in the right eye. This was also in a male, but there was no evidence of hereditary syphilis, though the patient was improving slowly on Donovan's solution.—Mr. LAWFORD referred to a case of a girl in whom vision had failed suddenly at the age of fifteen years, that of the right eye failing from $\frac{6}{6}$ to $\frac{6}{60}$. Minute light dots appeared at the macular region and persisted three weeks later. There was then no pigmentation. The case was still under treatment.

Mr. F. EVE and Dr. F. J. SMITH communicated particulars of a case of Obstruction of the Cavernous Sinus. After rheumatic fever, three years before, proptosis and double papillitis had come on, with headache and vomiting. There was, in addition, tenderness of the scalp and turgidity of the veins in the lids, with irregular general oculomotor paralysis, congestion of the fundi, and contraction of the fields of vision in both eyes. The obstruction may have been due to malignant disease of the pituitary body or to tubercle. Syphilis was excluded. Vision amounted to $\frac{6}{24}$ and $\frac{6}{12}$ in the right and left eye respectively.

Mr. DOYNE showed:—1. The effect of the Galvano-cautery in Conical Cornea. The instrument had been employed deeply three times and the resulting nebula was very faint. The operation had been performed at the age of eighteen years, and the patient, a young woman, was now aged twenty-six years. Vision was $\frac{6}{18}$. 2. Congenital Absence or Abnormality of the Puncta Lacrymalia without Epiphora.

Mr. LANG exhibited a peculiar case of Exophthalmos Proptosis occurring on Stooping or Compressing the Jugular Vein. Sometimes the proptosis occurred spontaneously; it then lasted some hours or days, was more painful, and was attended with disturbance of vision. There was now some post-neuritic atrophy.—Mr. THOMPSON, under whose care the girl had been, said the condition had commenced at the age of eleven years.—Mr. PRIESTLEY SMITH reported the case of a man in whom the left eye was sunken, but protruded when he bent forward; the condition had existed many years and had followed an injury to the head in boyhood. It was probably due to a varicose state of the ophthalmic vein.—Mr. TREACHER COLLINS mentioned the case of a young man he had recently seen whose sight failed on stooping. The eye projected and the lid also dropped, the deformity disappearing when the patient straightened himself.—Dr. HABERSHON referred the phenomenon to periodic turgescence of the orbital vessels.—The PRESIDENT referred to a case recently reported in an American journal.

Mr. C. H. WALKER showed a case of New Growth in the Yellow Spot Region in a middle-aged man whose sight had become defective two months ago. There had been no change since. The vision only amounted to "fingers" at thirty inches; there was a central scotoma, but no peripheral contraction of the field. The swelling at the macula was half as large again as the disc, and was raised 2 D above that of the rest of the fundus; it might either be a new growth or an inflammatory or cystic swelling.—Mr. ADAMS FROST thought the condition was one of central senile choroiditis.—Mr. HOLMES SPICER suggested that the doubt as to the cystic nature of the swelling might be settled by a puncture of the protrusion under ophthalmoscopic observation.—The PRESIDENT said he had seen cases exhibiting a similar appearance; he thought they were instances of senile choroiditis. One case at least was followed by atrophy and it would be interesting to know the sequel of the present one.

Mr. JOHN GRIFFITH showed a case of Retinitis Punctata Albescens. A man, aged forty-eight years, had had night blindness all his life. His parents were first cousins. One sister had a similar condition. The vision equalled $\frac{6}{24}$; the colour vision was normal; the optic disc was pale and waxy; the central region was crowded with very small, white, discrete dots; and the pigmentary changes were very slight.—Mr. TREACHER COLLINS had had a similar case in a young lady whose parents were first cousins and two of whose grandparents were first cousins. She had night blindness; there were also white spots in the fundus, as in this case.—The PRESIDENT said that the point about these cases was that they did not get worse, as the pigmentary ones did.

EPIDEMIOLOGICAL SOCIETY.

Diphtheria.

A MEETING of this society was held on April 30th, Professor J. LANE NOTTER, President, being in the chair.

Dr. LOUIS PARKES read a paper on the Infectivity of Diphtheria and the Relation of Diphtheria Prevalence to School Closure. In his parish of Chelsea, having a nearly stationary population of 75,000 persons, diphtheria had been present from January, 1890, to the end of September, 1895, though not as an epidemic, the cases ranging from 150 to 200 per annum, but in the following fifteen months two distinct epidemics, of three and six months' duration respectively, occurred, in which no fewer than 421 cases were notified. He did not attempt to distinguish between primary and secondary cases, preferring to class them as single and multiple, the latter comprising all occurring in a house within a month or usually within a week of the first case. In the non-epidemic period of five and three-quarter years there were 1153 cases, of which 209 (= 18·1 per cent.) were multiple, and in the epidemic period of nine months 421 cases, of which 168 (= 39·9 per cent.) were multiple, showing a greater degree of infectivity in the latter period. So, too, as regards the fatality, the deaths in the non-epidemic period were 222 (= 19 3 per cent.), and in the epidemic period 96 (= 22 8 per cent.), or, distinguishing between single and multiple cases in each period, the case mortality of these in the former period was 18 6 per cent. and 22·0 per cent., and in the latter period 21·3 per cent. and 25·0 per cent., diphtheria differing in this respect from scarlet fever, which was less fatal when most prevalent. As to age incidence, it appeared that in the non-epidemic years 56·7 per cent. were under ten years of age, but in the epidemic years 74·3 per cent. In both periods the case mortality among the multiple cases was higher under five years and lower above that age than among the single cases. Diphtheria epidemics were more localised than those of scarlet fever, persisting in each locality for three or four years and not spreading to adjacent districts until about two years from their commencement in the former. This epidemic, originating in Hammersmith, had thus slowly involved successively Fulham and Chelsea, but whether it would extend thence to Kensington remained to be seen. The closure of schools for the summer vacation of four weeks from the end of July was followed by a notable fall in the notifications in the thirty-third to the thirty-sixth week of the year, especially marked among children of school age. The influence of school attendance was well seen last year in June and July, when of 50 cases of children of school age 20 were among the girls and infants attending one of the Board Schools, the boys, who had a separate playground, with an entrance in another street, remaining exempt.

Mr. SHIRLEY MURPHY criticised Dr. Parkes's division of cases into single and multiple, which was likely to obscure important issues, and he differed from him as to closure of schools, which he believed to be most effective just when the disease was increasing in virulence.

Dr. HAMER maintained that many of Dr. Parkes's multiple cases were really primary, and derived from a common source with the first. In the epidemic at Lewisham he had no difficulty in distinguishing between primary and secondary cases, there having been in 66 of 68 houses an interval of over 48 hours between the first and following cases, and to have substituted 25 single and 60 multiple

Hosted by Google

cases for his 48 primary and 27 secondary cases would have deprived his inquiry of all value.

Dr. NEWSHOLME said that he believed strongly in school closure, and thought that several of Dr. Parkes's facts were capable of other explanations. Dr. Parkes laid too great weight on personal infection, ignoring the important factor of fomites and other external sources of infection, thus underestimating the number of primary cases.

Dr. R. DUDFIELD remarked that unfortunately the medical officer of the London School Board was opposed to the closure of schools.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

The Value and Safety of Abdominal Exploration in Obscure Cases.—The Principle of Anticipatory Gland Excision in Cancer Surgery.

A MEETING of this society was held on May 7th, Mr. W. BRUCE CLARKE, President, being in the chair.

Mr. L. A. BIDWELL read a paper on the Value and Safety of Abdominal Exploration in Obscure Cases. He brought forward a series of thirty laparotomies for diseases of the intestine, liver, stomach and kidney. In one case of gastro-enterostomy the patient died on the tenth day from bronchopneumonia, but all the others recovered. He had excluded cases of acute obstruction and diseases of the pelvic organs. The list included six operations for chronic intestinal obstruction, nine cases of exploration of the stomach, in three of which gastro-enterostomy was performed, eight cases of exploration of the liver, and seven cases of exploration of the kidney, in five of which nephrectomy was performed. He drew attention to the benefit which followed simple abdominal exploration in advanced malignant disease of the peritoneum where no curative operation was possible.—Mr. DORAN said he had found Langenbuch's incision very useful for exploring doubtful swellings in the region of the liver. It allowed the operator to explore both kidneys, which was always advisable, as he knew of a case where both were found diseased, so that the operator refrained from removing a tumour apparently omental. Mr. Doran pointed out the good results obtained by exploration in cases of tuberculous peritonitis. He inquired as to the method of suturing the abdominal incision adopted by Mr. Bidwell.—Mr. MCADAM ECCLES urged the necessity of informing the patient or his friends of the risks and advantages of an exploratory operation where the case was obscure. He dwelt on the occurrence of ventral hernia and intestinal adhesions following abdominal operations.—Dr. SNOW pointed out the occasional improvement which results after abdominal section in cases of malignant disease, even although the disease is not eradicated. He compared this with the recovery resulting from abdominal section in tuberculous peritonitis.—Mr. KEETLEY insisted on the importance of early diagnosis in abdominal cases, as so many were seen when the disease was too advanced for radical surgical treatment. Wholesale exploratory operations could not be advised. Many would be quite fruitless as it is precisely in the cases where nothing was to be found that the viscera would be most disturbed in trying to find something. Although septic peritonitis ought never to follow adbominal sections, extreme illness without peritonitis might be observed in hypochondriacal patients after abdominal exploration. There were other obvious objections to thinking as lightly of a laparotomy as of a laryngoscopic examination.—Mr. BIDWELL, in reply, said that as the cases narrated extended over a period of six years he had employed many methods of suturing the abdominal incision. He now generally united the peritoneum with a continuous silk suture, the remaining layers and skin being brought together by a single row of silkworm gut sutures. He had observed improvement in two cases of malignant disease after laparotomy where radical treatment was impossible.

Dr. HERBERT SNOW read a paper on the Principle of Anticipatory Gland Excision in Cancer Surgery.

PLYMOUTH MEDICAL SOCIETY.

The Case of Mr. R. B. Anderson.

A GENERAL meeting of this society was held on May 3rd to receive Mr. R. B. Anderson, F.R.C.S. Eng., Mr. J. H. MAY being in the chair.

After a few words of introduction from the Chairman Mr. ANDERSON gave a concise statement of the injuries done to him and the violations of his professional and civil rights; the circumstances of the case have already been fully set out in our columns. Mr. Anderson also gave details of the action of the Civil Rights Defence Committee and its efforts to obtain redress.

The CHAIRMAN said that all present had some acquaintance with the facts and the subjects dealt with, but he thought the cordial thanks of the meeting were due to Mr. Anderson for his clear, interesting, and eloquent address, and for the new light thrown upon the subjects. He was sure that the method of appealing to the great corporations for advice and help in maintaining the honour and true interests of the profession would have the approval of the meeting.

Mr. JACKSON said he could not but feel that this was a case of mutual interest to all medical men. They might say such a fate could not happen to them. Patients often said they had never thought, till it came, that the disease they suffered from would ever happen to them. If such things could take place there could be no greater security in the one respect than the other, and the sense of security was mistaken and dangerous. It was far better to take measures to prevent such possibilities. He begged to move the following motion as an expression of the views of the meeting:—

"This society, having heard Mr. R. B. Anderson's statement of his case, and of its important relations to other medical interests, desires to express the view that it concerns the honour and interests of the medical profession to support Mr. Anderson in his defence of rights essential to the practice of the profession; that their obligation to coöperate, and interest in coöperating, in this defence should be strongly pressed upon the General Medical Council, the Royal College of Surgeons of England, British Medical Association, and other great professional bodies, in pursuance of the policy adopted by the Select Medical Committee of the Civil Rights Defence Committee; and that this society and its members should actively coöperate in these representations by the appointment of a select committee to frame and present suitable memorials to the several bodies, by inviting subscriptions to a local fund in aid of the work of the Civil Rights Defence Committee, and by a suitable donation to head such fund."

This was seconded by Dr. LEWIS and carried unanimously.

Mr. Anderson and Dr. Smith were elected members of the society.

A committee, consisting of the chairman, honorary secretary (Mr. Woollcombe), the mover and seconder of the resolution, and Mr. Anderson, was appointed to give effect to the resolution, with power to add to their number. The meeting adjourned *sine die*.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Recovery after a Very Large Dose of Nitrate of Silver.—Complications following Operation for Varicocele.—Exhibition of Cases and Specimens.

A MEETING of this society was held on April 9th, Dr. BRAITHWAITE being in the chair.

Dr. ARTHUR DRURY (Halifax) gave an account of a misadventure which occurred to himself personally on March 21st, 1896. During the whole of the week previously he had been in bed with symptoms of tonsillitis, his temperature remaining at 101° or 102°F. On the above date it was decided to apply nitrate of silver locally. A new pencil was used, the weight of which was about 25 grains. This was put into a crayon holder, such as is supplied for the purpose in many surgical cases, but which did not happen to be in good order. Almost immediately the whole pencil slipped down the œsophagus. His feelings were absolutely indescribable. There was localised pain in the gastric region and a strong conviction that death must soon follow. Immediately a frothy foam welled up in large quantities forcing its way through the mouth and nostrils, staining handkerchiefs and the bed linen. There was an irresistible feeling that the pencil was lying impacted in the gullet. This seemed such a terrible source of danger that he insisted—against the wishes of those present—on having a probang passed. Mustard was given in large quantities and free vomiting induced. Some time afterwards common salt was given. A very careful search was made in the vomited matter for any of the

Hosted by Google

pencil which might have remained undissolved, but none was found. Collapse and great exhaustion followed. For some days afterwards a milk diet was carefully followed. Everything, especially if sweetened, had a very salty taste. There was no further vomiting, but there was very pronounced constipation. The temperature at once became subnormal and all the symptoms of the previous week's illness disappeared. During the next fortnight there was well-marked desquamation over the whole of the skin, though to the best of his knowledge there had been no exposure to scarlet fever and certainly no rash; and further, a child, not three years of age, was in and about the same room during the whole of the time without developing any symptoms. During the twelve months since the accident there have been many indications of dyspepsia; some of these symptoms, however, were present in a much less aggravated form prior to this. The pencil was composed of 4 per cent. nitrate of potash and the rest nitrate of silver. There was very little food or fluid present in the stomach at the time of administration. It was, therefore, a matter of surprise and interest that in this instance the recovery was so good. As, however, the cases in which so large a dose had been accidentally administered included many instances in which the death of the patient had resulted, a strong word of caution against the use of such a powerful corrosive poison in the solid form in throat affections was surely not out of place.

Mr. W. H. BROWN read notes of a case of Operation for Varicocele attended by Unusual Complications. The patient, a man, aged forty-two years, sought advice, about twelve weeks previously, complaining of pains in the left testicle. Upon examination a large varicocele and a shrunken testis were found. The history showed that his ailment was distressing him mentally very much. The patient was informed that his condition was not a dangerous one and he was advised to wear a suspensory bandage. A few days later his wife stated that for weeks past he had been constantly worrying himself about his condition, lying awake at night and at times talking very wildly, and that she feared that he was disappointed because something more had not been done for him. Eventually Mr. Brown excised and ligatured three or four enlarged veins. Ether was given as the anæsthetic, and the operation was without accident. In the evening the patient was comfortable, but his mental condition was most unsatisfactory, as he was rambling in his talk and extremely happy. That night he had no sleep, but was out of bed and walking about. Next morning the scrotum was as large as the head of a child at birth and was black, but there was no pain. Evidently his struggles had caused the ligatures on the veins to give way and a large hæmorrhage had taken place into the scrotum. His temperature was 103° F., and he was quite insane. Matters now went from bad to worse. Pneumonia attacked the right lung and caused additional anxiety. The body was covered with a rubeolar rash. Eventually the integuments of the scrotum with the greater part of the testicle sloughed, leaving a large granulating wound which completely exposed the right testicle. After this matters began to mend. The mental condition gradually began to clear and became quite natural. The parts affected were healthy, but some plastic operation would be necessary to protect and cover the exposed testicle. The treatment was directed towards the prominent symptoms, especially the insomnia, and the sloughing tissues were disinfected three or four times daily. Stimulants were given freely. Before operation all the usual investigations as to the urine, heart, digestion, &c, were made, and nothing to contra-indicate operative measures was found.—In the discussion which ensued Mr. JESSOP mentioned two cases of insanity following operations for varicocele.—Mr. LITTLEWOOD considered that varicocele might be a disorder likely to produce mania after operation; he related a case in which the whole scrotum had been torn off by an indignant wife, and recovery followed without operation.—Mr. PRIDGIN TEALE thought that the insanity was produced by the operation aggravating instead of soothing an already abnormal and irritable condition of the nerve centres.—Dr. DRURY suggested that the insanity might be partially due to the anæsthesia necessary for the operation.—Mr. MORTON considered that the pneumonia might be responsible for it.

Dr. CHURTON described a case in which Adherent Pericardium was diagnosed during life by the presence of Sir W. Broadbent's sign. He also showed the heart, which weighed fourteen ounces. The patient was a child, aged ten years. Old adhesions existed between the lower part of the left ventricle and the diaphragm. Death had followed recent pericarditis over the right ventricle, &c. The eleventh rib on the left side had been very clearly felt to be drawn in at each systole a few days before death. How long this sign had existed could not be ascertained.

Dr. CHURTON then showed the Lungs from a boy, aged twelve years, in whom a loud roaring pulmonary systolic bruit and very highly accentuated second sound were present during life, with hæmoptysis, epistaxis, and dropsy. The case was one of multiple aneurysm of the pulmonary artery, four of the secondary branches in one lung and three in the other leading into aneurysms as large as walnuts and filled with blood-clot.

Dr. CHURTON also showed an Appendix from a woman, aged twenty-three years, admitted with a history of two attacks of (supposed) appendicitis and complaining of inability to work on account of constant discomfort in the cæcal region. A fortnight in bed caused no improvement, and the appendix was removed by Mr. Mayo Robson. It was then found to be thickened at the end, and upon being opened showed a pellucid shining tumour, sessile, of the size of a small bean, obstructing the lumen three-quarters of an inch from the distal end, which was slightly distended by clear mucus and thickened. In water the growth swelled up to nearly three times its original size. There were no peritoneal adhesions or other signs of peri-appendicitis. The case was therefore one of myxoma of the vermiform appendix simulating recurrent appendicitis. No record of a similar specimen had been found.

Dr. R. H. HALL showed an unmarried woman, aged fifty years, with a perforation of the Nasal Septum the size of a two-shilling piece. It was first noticed four years ago and had steadily increased to its present size. There was no history of syphilis. He thought it might possibly be a rodent ulcer.

Reviews and Notices of Books.

The Life and Times of Thomas Wakley, Founder and First Editor of "The Lancet," Member of Parliament for Finsbury, and Coroner for West Middlesex. By S. SQUIRE SPRIGGE, M.B. Cantab., &c. With Two Portraits. London: Longmans, Green, and Co. 1897. Pp. 502. Price 18*s*.

IT would be obviously unseemly to review this book in the columns of THE LANCET. We are, however, desirous to make known to our readers the fact of its publication, and venture to do so by reproducing the prefatory note by ourselves which introduces the volume:—

"The occurrence in 1895 of the centenary of the birth of the Founder of THE LANCET seemed to us to afford a suitable opportunity of giving in the columns of the journal which he originated an extended record of his life and work. We placed the materials, some of which were easily accessible whilst some were obtainable only from senior members of our profession and others (to all of whom we wish to tender our sincere thanks), in the hands of our friend and colleague, Dr. S. Squire Sprigge, who is responsible for the biography, both in its serial and in its present form. For the great interest and pains which he has taken in the work we may express our gratitude to him. To venture any opinion on the quality of that work is not, we think, under the circumstances, within our province—the unprejudiced reader can judge for himself. We, the eldest son and grandson respectively of Thomas Wakley, cannot, in the ordinary course of human nature, be looked upon as free from bias. Indeed, such a thing would be impossible, for the senior of us was his constant companion until his death, and was associated with

Hosted by Google

him in his struggles and his work during the greater part of his public career. We have been anxious in two respects—firstly, that the services rendered to the cause of medical reform (and may we say to humanity?) by the subject of this biography should not, owing to the lapse of years, be lost sight of; and secondly, that the story of his life and work should be told by a biographer who would not view them through the imperfect lens of family affection. One word more. This biography of a man, most of whose work was done more than fifty years ago, may be considered belated, but whoever had written the life of Thomas Wakley much sooner would have incurred the chance of causing pain to many people."

The first of the two portraits is reproduced from a bust, a replica of one executed by John Bell, which stands in the hall of THE LANCET Offices; the second from an engraving by W. H. Egleton, from a painting by K. Meadows. To the latter is appended Thomas Wakley's autograph. The publishers have produced a volume which is handsome in appearance and well and clearly printed.

Compressed Air Illness. By E. H. SNELL, M.D. Lond., London County Council Medical Officer to the Blackwall Tunnel. London: H. K. Lewis. 1896. Pp. 251. Price 10*s.* 6*d.*

COMPRESSED air illness has only been recently investigated, but some of the symptoms were recognised soon after the invention of the diving bell in the sixteenth century. Hitherto no book has yet appeared in this country dealing with the subject, although with modern engineering exploits the disease has assumed considerable importance. Dr. Snell's appointment as medical officer to take charge solely of the compressed air work carried on at the Blackwall Tunnel has given him exceptional opportunities of studying the phenomena produced by a too long immersion in compressed air, and he has taken full advantage of such opportunities, and has done good service in publishing the result of his experiences. The matter has been approached from a purely clinical standpoint, and this is certainly wise, for, as he himself says, the physiological problems concerned are better dealt with in the midst of the quiet and resource of the physiological laboratory; any serious attempt to solve them in the rush and roar of a large engineering undertaking would indeed be futile.

The first chapter of the book is occupied with an interesting historical account of the disease and an excellent *résumé* of the physiological and pathological observations of previous observers. The second chapter gives a brief sketch of the description of work carried on in the tunnel, whilst the third contains a selection of cases of illness that occurred during the progress of work at the tunnel. The cases are very well described. Dr. Snell is a keen observer and from a perusal of them a good idea is obtained of the principal clinical features. True compressed air illness occurs during or after the decompression; it may commence immediately the exit air tap is turned, or may be postponed until some hours after coming out. By far the most common symptom is pain in the extremities, known by the men as "bends." A full description of this phenomenon is given. The injuries which may be sustained by the ear during the process of entry Dr. Snell regards as so obviously mechanical in their origin that he places them in a distinct class, not only on account of their time of onset, but also because of their distinctive pathology.

The causation of this illness is by no means as simple and uncomplicated as we might anticipate. The author lays stress on three etiological factors: the pressure itself, the length of stay in the compressed air, and the ventilation. Some previous observers laid much stress on a short exit process—that is, allowing a very short time for the reduction of the pressure in the air locks, but Dr. Snell is not of this opinion. He also shows that the amount of illness varies directly with the lack of ventilation of the compressed air chamber. The effect of age, too, is interesting, younger men being much less liable to be attacked than older men.

In regard to the pathology, favour is given to a set of theories which attempt to explain the symptoms by the increased solution by the blood of the gases contained in the compressed air. The chapter on Pathology is a most interesting one, and to anyone who wishes for information on the subject we cordially recommend it.

The treatment is naturally in a great measure a preventive one. The length of immersion is a most important detail and varies with the nature of the works, and the length of the shifts must be reduced until the desirable freedom from illness is met with. The maximum air pressure which can be endured with impunity has not been settled, but with our increased medical knowledge we are able to deal with pressures of 30 lb. and 35 lb. with far less harm than formerly. A large supply of fresh air is of course indispensable. With regard to curative treatment, if the case comes under notice soon after its commencement, there is one treatment that should immediately be resorted to—namely, recompression. At Blackwall this was carried out by means of a "medial air lock," of which a full description is given.

Taking the work as a whole, we congratulate the author on the result of his investigations. The book is a very readable one and one which ought to be studied not only by medical men who are likely to be brought into contact with such cases, but also by engineers and others who have the management and erection of works where labour in compressed air is necessary.

Lectures on Pharmacology. Vol. II. By Dr. C. BINZ. Translated from the Second German Edition by PETER W. LATHAM, M.A., M.D. Cantab. London: The New Sydenham Society. 1897.

THE appearance of the second volume of these lectures will without doubt be welcomed by all members of the medical profession, for it is a book which will appeal equally to the practitioner and to the student. Pharmacology is not a subject which usually makes pleasant reading, but in these lectures Dr. Binz has been most successful in producing not only a readable but at the same time a most interesting volume. The amount of information contained in the book is very great. The drugs are dealt with systematically as to their origin, preparations, properties, and actions. The actions are treated from the physiological rather than the pathological side, and full accounts of the experiments are given on which the conclusions of the therapeutic actions have been based. The action of quinine upon the lower organisms is fully described, especially with regard to malaria, and diagrams are also given which illustrate the inhibitory power which quinine possesses over inflammatory processes. Dr. Binz also carefully sums up the evidence as to the mode of action of iron in chlorosis, and his conclusions upon this point are as follow:—"It is probable (1) that the functional activity of the blood-forming organs, which is lowered or suppressed in chlorosis, requires a stimulus or impulse; (2) that iron, when carried in the circulation to these organs in increased quantity, acts as a chemical stimulus and, not being an entirely foreign constituent, is less injurious in its action than other stimulants." As evidence in support of this view Dr. Binz refers to the fact that chlorosis may be also cured by other substances, such as arsenic, phosphorus, and mercury, although these drugs are not constituents of hæmoglobin.

Hosted by Google

The concluding chapter deals with the methods in which the science of pharmacology may be best advanced, both experimentally and clinically, and the author gives his views as to the different lines which should be followed.

Archiv für Schiffs- und Tropen-Hygiene, unter besonderer Berücksichtigung der Pathologie und Therapie. Herausgegeben von Dr. C. MENSE, Cassel. Band I., Heft 1. (*Archives of Maritime and Tropical Hygiene.* Edited by Dr. C. MENSE, Cassel. Vol. I., Part 1.) January, 1897. Cassel: Th. G. Fisher and Co. 1897. Price 12*s.*, annual subscription.

NOT a year passes without many new additions being made to the list of periodicals devoted to one or another branch of medical science. The journal before us has been established to disseminate information concerning subjects of importance to those concerned in maritime travel and colonial enterprise. The editor in his prefatory remarks points out how essential such knowledge is becoming for a state like Germany which is aiming at extension in these directions. The number contains a study of malarial fevers in the tropics by Dr. A. Plehn, a military medical officer in the Cameroons, especially in regard to the practical importance of examination of the blood. As supplementing this article, there is an editorial appeal to readers in tropical countries to collect material for despatch to the mother-country, full directions being given on the mode of preservation of the specimens asked for. Dr. Nocht of Hamburg contributes an article upon Sanitary Police Measures in vogue for preventing the importation of infectious disease by sea, in the course of which he describes the quarantine and other regulations adopted by various countries. A description of Coolie hospitals in Sumatra by Dr. L. Martin and a paper on Beri-beri by Dr. Max Glogner complete the original articles, the number also containing several reviews and abstracts of recent writings on subjects within the special domain covered by the *Archiv*. The journal is to appear every two months.

An Account of the Life and Works of Dr. Robert Watt. By JAMES FINLAYSON, M.D. Glasg. London: Smith, Elder, and Co. 1897. Price 3*s.* 6*d.*

WE heartily commend this biographical sketch of a remarkable man to the notice of our readers, for the author of the "Bibliotheca Britannica" deserves to be remembered, although we venture to say that to many who have had reason to be grateful to him for his self-imposed labours his personality is quite unknown. He died at the early age of forty-five years, just as his *magnum opus* was on the eve of publication, and for more than half a century that work remained without a rival as the most compendious bibliography of British literature. We learn from this memoir that Robert Watt was born in 1774, the youngest son of a farmer in Stewarton in Ayrshire, that his early love of literary pursuits led him from the carpenter's shop to the university, and that after a brief experience of the scholastic profession he turned his attention to medicine, and entered on general practice at Paisley. In 1808 he published a monograph on Diabetes, which attracted some attention, and in 1810, having obtained the M.D. degree from King's College, Aberdeen, he established himself as a physician in Glasgow, where he lectured on the Theory and Practice of Medicine. The preparation of a catalogue of his medical library for the use of his students seems to have been the nucleus of his greatest literary achievement, which began with the endeavour to frame a catalogue of medical works by British writers, and subsequently embraced other subjects. To the preparation of this work he devoted all his leisure time for many years, and it is interesting to read that long after his death his MSS. were collected and placed in the Free Library at Paisley. Amongst other work that he accomplished, that which has perhaps attracted most attention was his statistical enquiry into child mortality at Glasgow during a period of thirty years, published in 1812 in an appendix to a "Treatise on Chincough." This inquiry was based on a laborious investigation of the death registers of the Glasgow parishes, and embraced the years prior to, and subsequent to, the introduction of vaccination. Himself strongly impressed with the value of vaccination, which was borne out by his research showing a remarkable decrease in child mortality from small-pox, he found that the total deaths at this period of life had not fallen off, the diminution in small-pox being largely counterbalanced by a rise in the numbers dying from measles. The publication of these statistics was deprecated by Jenner as tending to discredit vaccination, and they have often been quoted in the same sense by Jenner's opponents; and yet it is clear that they indicate only the increase of another zymotic disease, which as a cause of infantile mortality may be said to have taken the place of small-pox. Dr. Watt founded a medical society in Glasgow, became physician to the Royal Infirmary, president of the Faculty of Physicians and Surgeons, and of the Glasgow Philosophical Society. The list of his writings appended to the memoir (which also contains his portrait) shows that in addition to his great bibliotheca he contributed much to professional literature.

LIBRARY TABLE.

Sprachführer für die Ärztliche und Pharmaceutische Praxis. Deutsch-Englisch und Englisch-Deutsch. (German and English Vocabularies of Words used in Medicine, Surgery, and Pharmacy, together with Dialogues in both Languages between Patient and Medical Attendant). Von GISBERT VON SUDTHAUSEN. Leipzig: Eduard Besold. 1896. Two vols. Pp. 132 and 134. Price 4.80 marks.—These little volumes can be well recommended as explaining a large number of technical terms which are not to be found in the ordinary dictionaries, whether English or German. The work might, however, have been considerably improved if it had been finally revised by some English person conversant with the subjects, who would no doubt have suggested several minor emendations, and would have corrected such inelegancies as "the blind-gut" (der Blinddarm—i.e., the cæcum), "the chin-beard," "the ear-shell" (die Ohrmuschel—i.e., the external ear or auricle), and "the great-gut" (der Dickdarm—i.e., the colon). These occur on the first three pages of the English-German part, and there are others of a like kind, such as on pp. 6 and 7, "the phlegm" (der Schleim—i.e., mucus), "the pituitous tunic" (die Schleimhaut—i.e., mucous membrane), and "the strait-gut" (der Mastdarm—i.e., the rectum). The lists of surgical requisites and of pharmaceutical appliances and preparations are tolerably full. The anatomical and pathological part is also well selected as far as it goes; but in consequence of the space taken up by the dialogues this section is not so copious as that given in the German-English Medical Thesaurus, by the Rev. Henry Losch, M.D., of Philadelphia, which was reviewed in THE LANCET of Feb. 1st, 1896, p. 300.

Atlas der Klinischen Untersuchungsmethoden nebst Grundriss der Klinischen Diagnostik und der Speziellen Pathologie und Therapie der Inneren Krankheiten. (*Atlas of Clinical Methods of Investigation, with Elements of Clinical Diagnosis and the Special Pathology and Therapy of Internal Diseases.*) By Dr. CHRISTFRIED JAKOB. München: F. J. Lehmann. 1897. Price 10 marks.—As the name indicates, this is an atlas illustrating the methods of physical diagnosis. The plates are small, but their

Hosted by Google

execution is excellent. The student can see at a glance how an examination ought to be conducted. The contractions used in the text are numerous, but when once understood are easily followed. We have never seen better illustrations of the urinary sediments and of the objects met with in the examination of sputum. It is a work which would prove very useful to the practitioner and to the student, and for those who have a knowledge of German we can cordially recommend it. It forms one of Lehmann's "hand atlases"—a truly wonderful series of books. The number now under consideration is the fifteenth volume, and contains no less than 182 beautifully coloured illustrations engraved on 68 plates, and in addition there are 64 diagrams in the text.

JOURNALS AND REVIEWS.

The Journal of Anatomy and Physiology. Conducted by Sir WM. TURNER and Dr. J. E. M'KENDRICK. Vol. XXXI. New Series, Vol. XI., Part 3. April, 1897. London: Charles Griffin and Co. Price 6*s*.—The first article in this number is an important one by Professor Rutherford on the Histology of Muscle, in which he gives the results of his researches on this difficult subject, with many illustrations. He dissents from the views of Professor Schäfer, and inclines to those of Dobie, to whom Professor Rutherford dedicates his communication. Professor Bertram Windle, of Mason College, Birmingham, supplies a few notes on the Myology of Dolichotis Patagonica and Dasyprocta Isthmica. Dr. A. A. Gray, of Glasgow, continues his investigation into some of the Principles of Auscultation. Dr. David Fraser Harris, of Glasgow, has a note on the Reducing Power of the Tissues, and also one on Hæmatoporphyrinuria and its Relations to the Source of Urobilin. Mr. Peter Thompson of Owens College, describes a case of Polypus of the Pylorus with Intussusception. Dr. Robert A. Fleming supplies an article on the Histology of Medullated Nerve Fibres in Man and Rabbits derived from a study of their pathological anatomy. Mr. W. M'Dougall contributes an article on the Structure of Cross-striated Muscle and a Suggestion as to the Nature of its Contraction. Dr. Francis Dixon, of Trinity College, Dublin, describes a Rare Condition of the Vermiform Appendix. Dr. Caton of Liverpool describes a Case of Complete Transposition of Viscera. An abstract of a paper by Dr. Robert Kennedy on the Regeneration of Nerves is supplied by Professor M'Kendrick. And lastly, Professor Bertram Windle gives his Seventh Report on recent Teratological Literature. Four sheets of the index to Vols. XXI.–XXX. are appended to this number of the Journal.

The *Nineteenth Century* for this month, among several interesting articles, contains one from the pen of Mr. Malcolm Morris which will specially appeal to medical readers, entitled The Progress of Medicine during the Queen's Reign. Taking as a text the words of H.R.H. the Duke of Cambridge[1] on the occasion of the opening of the new operating theatre in St. George's Hospital, "I do not believe that amid all the improvements, the advantages, and the additions that have occurred during the long reign of Her Majesty, anything has made so much progress as medical and surgical science," Mr. Malcolm Morris shows the main directions in which that progress has occurred. Improvements in surgery have been due to the discovery of anæsthesia or the artificial suppression of pain, and antisepsis or the prevention of septic processes in wounds, and of the history of these two marvellous developments a readable and attractive summary is made. Passing from surgery to medicine, Mr. Morris says that he has to chronicle "an advance in knowledge if less striking than in surgery ..... not less real," while it must be remembered that the progress had to commence from much further back. For even if we cannot quite endorse the author's opinion that "when the Queen came to the throne in 1837 it is hardly too much to say that the average medical practitioner knew little more about the diseases of the heart, lungs, stomach, liver, and kidneys than was known to Hippocrates," there is no doubt that in the thirties surgery was incomparably ahead of medicine. Mr. Morris attributes the more obvious improvements in our medical treatment to the invention of the ophthalmoscope and the laryngoscope and the perfection of microscopic and stethoscopic procedure. The article is very opportune at the present moment when so vehement an appeal is being made to the public for the support of the London Hospitals. All who read it will see that the science of medicine, under which term we include not only surgery and midwifery, but all the ancillary sciences, has deserved well of the people during Her Majesty's reign.

[1] THE LANCET, Dec. 26th, 1896.

The Monist.—Professor Rudolph Eucken of Jena contributes a long and learned essay on Hegel. It seems that "just as his [i.e., Hegel's] system of the absolute intellectual process, by positing a formal reason, a conformity to law, and a progressive movement in the All, totally converts reality into reason, so also it cherishes the belief that it has cleared up by the world's movement itself everything that is dark." Dr. Paul Carus, the editor, writes on the Mythology of Buddhism. He considers that Buddhism "offers a complete philosophy, which is an outspoken positivism with decidedly anti-metaphysical tendencies. It propounds a psychology which is worked out in its most important details, and is quite up to date. ..... In addition to all this, Buddhism has developed an exuberant mythology." This article is profusely illustrated with grotesque engravings. Dr. James Cappie of Edinburgh has a lengthy paper on Intracranial Physics, in the course of which he endeavours to explain the phenomena of sleep by changes in the venous circulation of the pia mater.

Knowledge for May contains two contributions to the series of articles appearing in that magazine on the Science of the Queen's Reign. The first article is by Mr. R. Lydekker, F.R.S., and deals with Biological Progress; the second, by Mr. A. J. Cole, F.G.S, deals with Sixty Years of Geological Research. These articles are illustrated with portraits of Charles Darwin and Sir Charles Lyell.

Mercy and Truth.—Dr. T. L. Pennell describes the Afghan Medical Mission at Bannu, and there are also articles dealing with the experiences of medical missionaries at Gaza and in Persia.

THE BRITISH INSTITUTE OF PUBLIC HEALTH.—The council of the institute have made arrangements to hold a meeting in the Guildhall of the City of London on Wednesday, June 16th, at 3 P.M., at which an address will be moved to Her Majesty in connexion with the great progress made in Public Health matters during the past sixty years. The Right Hon. the Lord Mayor of London (who will preside) and the Sheriffs will attend in state. In the evening the annual dinner will be held in the Carpenters' Hall, London-wall, tickets for which, inclusive of wine, are 25*s*. In view of the limited accommodation it is desirable that those who wish to be present should make application at once to the Secretary, Mr. C. A. James, at 20, Hanover-square, W. The Harben Lectures will be delivered in King's College, London, by Dr. G. Sims Woodhead, Harben Lecturer for 1897, Director of the Research Laboratories of the Royal Colleges of Physicians and Surgeons of London, on "The Bearing of Recent Bacteriological Investigations on Public Health Work, especially in connexion with (*a*) the Diagnosis and Treatment of Diphtheria; (*b*) the 'Stamping out' of Tuberculosis; and (*c*) Biological 'Filtration'" at 4 P.M., on the following Wednesdays: June 23rd and 30th, July 7th and 14th.

THE LANCET.

LONDON: SATURDAY, MAY 15, 1897.

IF the profession is to be kept a profession and if its members are to be protected and delivered from the manifold evils which threaten their peace and prosperity it seems more and more essential that everything should be done by each member in his personal or official capacity to promote union within our ranks. If this can be procured and preserved we should be the strongest profession of the three, instead of which we often appear the weakest and the least coherent. The other professions are essentially more public in their relations and have opportunities of asserting themselves which ours has not. But it is a fact that if we could but be true to one another and to the duties which we have to perform we could make ourselves more indispensable than men of other callings and put ourselves in a position to command the full respect of the public and reasonable terms for our services. This is so obvious that we are driven to ask: What are the circumstances of the medical profession that hinder its prosperity and break it up into weak and inefficient sections? Answers to this question will vary somewhat according to the point of view of him who tries to answer it. We may indicate the principal ones that occur to ourselves from a point of view that is a fairly broad one. First, it is undeniable that specialisation of professional work is a dividing influence. The specialist, without always intending it, is apt to act apart and view a particular case through his own special glasses, so to speak. The specialists intensify this tendency by organising their specialties to a high degree and cutting themselves off from the general life and society of the profession. They come to be a class apart and are more apt than the general consultant to lose sight of the general practitioner, who is responsible for the general health of the patient and has the right to be regarded when any special evil arises. We do not deny for a moment that there are many specialists who are scrupulously courteous and considerate in this matter. We admit it cheerfully. But we indicate a tendency in specialism to divide the profession into sections marring its oneness and its strength.

Another cause of division is the question of hospital abuse. A certain proportion of the profession, an ever-increasing proportion, are connected with hospitals in the capacity of honorary medical officers, and often also as clinical teachers. Men in this privileged position naturally look at the hospital in a somewhat different light from that of the general practitioner: it is a vantage ground to them, it brings them position, it brings them patients, it supplies a field for their labours in medical education, and it is often the road to practice and even to fame. That there should be a few thousand patients, more or less, going unfitly and unworthily to hospitals to swell their *clientèle* and to afford the raw material of clinical education or of fame does not matter much to hospital consultants as a class, or, at least, to the leaders among them, who are safe in the enjoyment of reputation and of good fees. It is otherwise with the struggling general practitioner. He sees in these unfit and unworthy thousands the materials of general practice, for which he has been trained by the very teachers who now treat gratuitously the people who should be his patients and pay such sums as would meet the modest wants of his early professional life. As he gets older he sees more respectable patients demoralised by the same facilities and attractions, and he comes to regard the hospital consultant not indeed as his natural enemy, but as one whose interests are different from his own. This is not really the case, but it seems so, and the two classes come to think of each other, and sometimes speak of each other, as if in rival camps.

A third cause of division in the very rank and file of the profession is the excessive number of its members and the unprecedented competition involved. This competition has been intensified by pernicious forms and methods of practice which contemplate crowds of patients and the smallest pittance of remuneration—conditions which are inconsistent with care in the investigation of cases and with anything like that consideration for sick persons which humanity and the medical art alike require. Sometimes these forms of practice are conducted by individuals in a purely private way and on their own responsibility. In other cases huge associations are formed on a commercial basis, either by friendly societies or by purely commercial companies, the agents of which canvass districts in a wholesale manner and take away the patients of resident practitioners. The gentlemen who serve these societies or companies would not individually canvass the patients of other medical men; but in accepting office they endorse canvassing methods and accept responsibility for them. Hence arise much discord and division in the profession.

The call to union which we venture to utter is, it will be seen, spoken in no ignorance of the elements of division in the profession; but it is spoken with a deep conviction that with a little forbearance and patience these elements will be overruled by the consideration of members in every branch of practice. We are all of one profession. We are dependent one on another. The consultant and the specialist (at least in some departments of practice) and the general practitioner are all necessary to the patient and can all be helpful to each other. They can all contribute to the solution of this scandal, hospital abuse. And there are many proofs that all are trying their very best to do so. What is wanted is some friendly consultation and, let us add, some mutual concession; in other words union. The remarkable communication last week of our Special Commissioner shows us that in France and in Belgium there is more organisation than with us—though that this is not an invariable case may be seen from the letter of our Paris Correspondent this week. Our very excess of freedom as a nation makes the assertion of individual opinion a little excessive for practical and professional purposes. Let us control it and work towards the common end of making medicine in all its branches a dignified, efficient, and united profession.

The man who, sitting on a branch, proceeds to saw it through between himself and the tree has not been

Hosted by Google

deemed wise any more than his immediate relative who kills the goose that lays the golden eggs. But both of them may be glad to find that they are not without kinsmen in the Italian kingdom if a Bill now before its Chamber of Deputies should pass into law. That Bill proposes to make it illegal—in other words, impossible—for a non-Italian medical man to practise in Italy unless he holds an Italian qualification, virtually compelling the foreign resident or visitor (who in ninety-nine cases out of a hundred is of English-speaking nationality) to rely in case of illness on the native practitioner. Now, as we have already pointed out,[1] this is a suicidal step on Italy's part. From twelvemonth to twelvemonth there are rather less than half a million—say, 450,000—citizens of the English-speaking world within her borders, some of them resident, but the vast proportion of them migratory, whose stay is limited by months or even weeks. Taking the estimate of the British and American consuls that these foreigners spend £50 apiece during their stay—a very safe estimate, if avowedly an approximate one—we get a total of £20,000,000 sterling annually poured into the coffers of Italy—replenishing the flaccid circulatory system every "season" and keeping her in what financial well-being she enjoys for the rest of the year. A very large proportion of these "paying guests" come for health; many others, owing to various causes, incur illness grave enough to require medical advice; and all of them are sustained by the confidence that in the great central resorts, at least, if not at every marine sun-trap, they have a well-qualified compatriot practitioner within hail. Is it for a moment to be imagined that they would arrive in such numbers if there were no English-speaking medical men with a sound qualification from the home country to call in? Can a greater deterrent to their visits be conceived than their compulsory recourse to the Italian-bred practitioner in case of illness or even accident? The said practitioner may be a MORGAGNI in the laboratory or a BAGLIVI by the bedside, but the very fact that he is Italian—rarely speaking English or even the French which EDMOND ABOUT found so "comical"—is quite enough to impair the confidence which, particularly in a foreign country, the patient (small blame to him) requires. Impose it as a condition on sojourning in Italy that no English-speaking practitioner shall in any case of illness be available, and the 450,000 annual "paying guests" of the same tongue will shrink to less than a third of that total. The Italian revenue is not so flourishing that it can afford to lose annually some £14,000,000 of gold.

An attempt is being made by the proposers of the Bill just introduced to vindicate its provisions on the ground that in England no Italian physician can practise without a British qualification. We do not know that the Italian colony in London, for example, is debarred from consulting a compatriot practitioner, unplaced though he be on the British Medical Register. But the parallel sought to be established between the two countries does not exist. If English-speaking practitioners in Italy attended Italian patients, or if Italian practitioners in the British Isles attended English-speaking patients the "argumentum ad hominem" might hold. But no such "poaching on each other's preserves" prevails. All the English-speaking sojourner in Italy requires is that he shall have the power to call in a practitioner of his own nationality, and the numerous "colonies" of such sojourners make it eminently reasonable. On the Riviera Levante and Ponente every winter there are sun-traps which are virtually "suburbs of London," and in the great centres — Venice, Florence, Rome, and Naples—the English-speaking community is always a considerable proportion of the population. It is numerous enough to maintain several chaplaincies or churches—Anglican and dissenting; it has its own isolated and characteristic life as much as in the country of its origin. The watchword of "L'Italia ai Medici Italiani" may have practical effect, and the *clientèle* of Italian physicians may remain unencroached upon by any outsider without depriving these "suburbs of London" on Italian soil of the right to consult the practitioners they import. There, indeed, lies the whole case for the *status quo* which Italian legislation is seeking to subvert. The members of the English-speaking colony in Rome or in Florence do not lose their nationality because they live on Italian soil; nor do they forfeit their right to employ compatriot practitioners any more than to attend compatriot places of worship, or to recruit their domestic *personnel* from compatriot service. If they sojourn in Italy as guests they do so as "paying guests," amply rewarding the hospitality vouchsafed them not only by the money they bring freely and spend handsomely, but (as Italians themselves admit) by importing and maintaining a higher standard of civilisation, from hygiene downwards, than the mediæval traditions prevalent around them.

Yes, it would be a black day for Italy if she alienated from her soil and her social life the English-speaking element to which she owes so much; and we look to sensible, right-feeling, and patriotic Italians for that exposure and rejection of the "anti-English-practitioners" Bill which the DI RUDINI Government, we are sorry to see, is disposed to consider favourably. The hotel-keeping and commercial interests are sufficiently strong in political representation to make effective fight against a measure so disastrous to their prosperity; and if they succeed in preventing its becoming law they will have done more for their country than the "patriotti da piazza" (patriots of the city square) and the "politici da caffè" (coffee-house politicians), whose narrow Chauvinism, to judge from their organs, is so gratified by the Bill.

A SUBJECT of perennial interest has recently been under discussion in Liverpool. It appears from a report made to the Local Government Board by Mr. FULLER, the inspector to the Board, that a large proportion of the children in the Workhouse Schools, the Kirkdale Industrial Schools, and the Leyfield Poor-law Schools had been suffering from severe ophthalmia and from granular lids, and he further stated that in his opinion both forms of the disease were infectious. Dr. ALEXANDER, the medical officer to the Workhouse, so far as we can gather from the somewhat meagre account

[1] THE LANCET, Dec. 19th, 1896, p. 1774.

Hosted by Google

that has reached us, wrote a reply to Mr. FULLER, in which he protested against the assumptions and allegations made in the report; and at a conference of the members of the Select Vestry, the Workhouse Committee, and of the Industrial Schools Committee, when Dr. ALEXANDER had the opportunity of meeting Mr. FULLER, he elicited from Mr. FULLER the statement that he considered granular lids in all stages were contagious or infectious, even when no discharge was visible. To this statement Dr. ALEXANDER took exception and went so far as to say that Mr. NETTLESHIP, Mr. SWANZY, and all the other experts held a contrary opinion. Dr. ALEXANDER was supported by Dr. MCMURRAY, the medical officer of the Kirkdale Industrial Schools, and by Dr. MAHONY, the medical officer of the Leyfield Poor-law Schools, both of whom maintained that granular lids were not contagious, and that when they developed into acute ophthalmia the children were isolated and subjected to special treatment so far as the space at disposal and other circumstances permitted. Making allowance for the meagreness of our authority, which does not, perhaps, render justice to the opinions expressed by medical men upon a technical subject, it appears to us that Mr. FULLER is in all points right in the view he has taken in his report. All recent evidence tends to show that trachoma (granular lids) is a disease attributable to some form of micrococcus, not improbably the gonococcus of Neissen, and that it is contagious in its nature both in the acute and in the chronic stages even when no discharge is visible. We fail to find in the authorities quoted by Dr. ALEXANDER any statement to the effect that in either stage, acute or chronic, the disease is non-contagious. There is, indeed, another form of conjunctivitis, known as follicular conjunctivitis, which chiefly affects the mucous membrane of the lower sinus of the conjunctiva and often undergoes spontaneous cure without leaving any cicatrix; but even this disease is generally held to be contagious. In any case where several children in a school presented granulations on the inner surface of the lids whilst some of them developed acute ophthalmia, we should consider that either true contagious ophthalmia or that follicular conjunctivitis was present, and that not only those who presented the acute stage with free purulent discharge, but those in whom the presence of granulations was only discovered by eversion of the lids, and those, also, in whom the disease was on the decline, should one and all be separated from those who were free from any sign of disease; and further, that unless there was clear evidence of its introduction from some infected individual a thorough inspection of the whole building in regard to the adequacy of ventilation both by day and night, the arrangements for washing and the use of towels, and the system of diet and exercise in force should be carefully considered, and such improvements made as might be thought advisable. In a large proportion of cases there can be little doubt that overcrowding, dark and ill-ventilated rooms, damp soil, and insufficient diet are very efficient agents in developing and in promoting the extension of the disease. How far these conditions obtain in the institutions referred to in Mr. FULLER'S report we have no means at hand to determine.

Annotations.

"Ne quid nimis."

THE PUBLIC HEALTH (SCOTLAND) BILL.

LAST week we pointed out that the House of Commons Committee sitting on this Bill had agreed by a small majority, including the Lord Advocate, that in future Scotch towns might, with the sanction of the Local Government Board, appoint medical officers of health without any qualification in public health. We added that any further tendency to sanitary retrogression would have an opportunity of showing itself with regard to the question of the powers of sanitary inspectors, of whom the law requires no qualification of any sort. The inspectors had issued a document in which they asked to be invested with the statutory duty of certifying whether any manufactories or trade premises or processes within the district of the local authority might be injurious or dangerous to health. The proposal that certification of this sort should be permitted by statute to unqualified persons we ventured to characterise as preposterous. Nor have we changed our opinion. But in the view of the Committee and the Lord Advocate the proposal was distinguished not by audacity but by blushing modesty. The suggestion referred to only a single one of eleven classes of nuisances specified in the 16th Section of the Bill. The Committee are of opinion that it should apply to *all* the classes of nuisance—premises of any sort dangerous or injurious to health; wells or water-supplies similarly injurious or dangerous; accumulations or deposits of every sort; school-houses; factories or workshops, &c., not under the Factory Acts; fireplaces or furnaces; chimneys; and churchyards so situated or crowded or conducted as to be offensive or injurious or dangerous to health. That a man who was one day a tinker or a tailor and the next day a sanitary inspector would at once be endowed with powers enabling him to protect the community to this wide-reaching extent was very obvious to the Lord Advocate we presume, for no printed notice of the amendment was given. A member of Committee rose and made the proposal, and the representative of the Government forthwith accepted it. It is perfectly clear that the universities and corporations have been all wrong as to what constitutes a qualification in public health. The General Medical Council has been insisting on a longer curriculum and more difficult examinations in sanitary science. They have been utterly at sea. No curriculum and no examinations are necessary. They have added a requirement that apprenticeship to a medical officer is an essential preliminary. In the opinion of the Government, as voiced by the Lord Advocate, an apprenticeship to a shoemaker or a barber would be quite sufficient. The medical officer of health with his double and triple qualifications and his knowledge of the causes of danger and injury to health and of chemistry and bacteriology is in future, in the eye of the law in Scotland, to be placed in the same position with the man who, having perhaps been a failure as a tradesman or a shopkeeper, has been able, through some remote relationship to some member of the local board, to get himself appointed as the sanitary inspector of a petty borough. May we venture to suggest to the Lord Advocate that he should go a little further and try to get Parliament to set the town scavenger at the head of the public health service, or, carrying the same principle into the profession of law, should resign his own post as Lord Advocate in favour of the boy who sweeps the steps of Dover House? Meanwhile, to that part of the population in Scotland which is so unfortunate as to ow

Hosted by Google

"premises" of any sort, or wells, or water-supplies, or animals, or manufactories, or trades, or fireplaces, or furnaces, the prospects of wholesale certification by such officials must be nothing less than alarming. We commend the printed proceedings of the Committee to the attention of all concerned, and look forward with whetted curiosity to their doings with regard to the 150 clauses which yet remain.

LORD LISTER AND HIS ASSISTANTS.

WE have already announced that a complimentary dinner is to be given to Lord Lister by his former house surgeons, clinical clerks, and dressers. It is now decided that the dinner will be held at the Café Royal, Regent-street, on May 26th, and we are informed that the arrangements are so well advanced that it promises to be one of the most interesting tokens of regard which have been offered to the President of the Royal Society during the year made memorable to the medical profession by the gratifying recognition of his splendid work. Much difficulty, however, has been experienced by the committee in obtaining correct lists of those who have held subordinate office under Lord Lister. In some cases it has been impossible to trace their addresses. The committee, therefore, hope that all who have worked under Lord Lister as house surgeon, clinical clerk, or dresser, whether in Glasgow, Edinburgh, or London, will consider themselves invited to join in the movement, and will not wait for a personal request to do so. If, unfortunately, they should not be able to attend the dinner they are requested to intimate the dates of their offices, as it is proposed to draw up and print as a souvenir of the occasion a complete list of all who have been intimately associated with the father of antiseptic surgery since Lord Lister's first tenure of hospital office in 1861. All particulars concerning the dinner can be obtained from the honorary secretary, Dr. St. Clair Thomson, 28, Queen Anne-street, W.

CLAIM TO BE REGISTERED UNDER THE DENTISTS ACT.—THE QUEEN *v.* THE GENERAL MEDICAL COUNCIL.

AN important question has been raised in the High Court of Justice before Mr. Justice Hawkins and Mr. Justice Wright, and decided in favour of the view of the General Medical Council.[1] The case was that of Mr. Isidore Spero, who had obtained a rule *nisi* for a *mandamus* against the General Medical Council commanding them to show cause why they should not place the name of the applicant on the Dentists' Register. Under Clause C of Section 6 of the Dentists Act a person is entitled to be registered who "is at the passing of the Act (1878) *bonâ fide* engaged in the practice of dentistry or dental surgery, either separately or in conjunction with the practice of medicine, surgery, or pharmacy." By Section 7 information of the facts of the case of persons claiming to be registered under Clause C of Section 6 must have been sent before Aug. 1st, 1879. Section 37 provides that "any person who has been articled as a pupil, and has paid a premium to a dental practitioner entitled to be registered under the Act in consideration of receiving from such practitioner a complete dental education, shall, if his articles expire before Jan. 1st, 1880, be entitled to be registered under the Act as though he had been in *bonâ-fide* practice before the passing of the Act." It was argued by Mr. Walter Chitty in support of the rule that Section 7 could not have been intended to apply to persons claiming to be registered under Section 37. But Mr. Justice Hawkins, in discharging the rule, pointed out that the person entitled to be registered under Section 37 was entitled to be registered "as though he had been in *bonâ fide* practice before the passing of the Act." There was no reason, therefore, why such a person should not be under the same obligation to make a declaration under Section 7. A point was made of the wording of the schedule giving the form of declaration to be signed by a person claiming to be registered on the ground that he was engaged in the practice of dentistry at the time of the passing of the Act. But Mr. Justice Hawkins did not think it a good one, as the declaration was to be made in the form provided or "to the like effect." The form could easily have been varied to suit the pupil in question, who did not apply for registration before August, 1888. His term of pupilage, three and a half years, commenced in April, 1875. Mr. Justice Wright was of the same opinion, but he reserved the point as to the obligation of pupils whose articles did not expire till after Aug. 1st, 1879.

[1] See the *Times*, May 8th, 1897.

THE VITALITY OF THE TURKS.

AMONG the many services done to the Turks by Greece in the last few weeks not the least is to have given them an opportunity of showing how and what they can endure. The *Times* correspondent is much struck with their eagerness to fight and with the difficulty of killing them. He mentions one man whose abdomen was penetrated by a bullet, and who not only kept his place in the ranks till the battle ended but marched ten miles afterwards. Another man with three wounds—two in the legs and one in the shoulder—continued on duty twenty-four hours until an officer noticed his condition and sent him to hospital. Sometimes our alcoholism has been associated with our daring and our endurance as cause and effect, but here are qualities of the same sort in a non-alcoholic nation. Our contemporary's correspondent remarks further on the rapidity with which wounds heal, and says that medical men attribute it to the abstemiousness of the Turks. Here we should scarcely be able to match the race whose soldiers are ill clad, ill fed, and who take no alcoholic stimulants.

ATROPHY OF THE OPTIC NERVE FOLLOWING EXPOSURE OF THE EYE TO DIRECT SUNLIGHT.

IN the lately issued number of the Royal London Ophthalmic Hospital Reports Mr. Treacher Collins publishes a case of considerable interest, in which impaired vision and central scotoma followed somewhat prolonged examination of the sun with the unshaded eye. The patient was a schoolmistress, aged forty-nine years, who one day early in May, 1889, about four or five o'clock in the afternoon, on casually glancing at the sun noticed that it was surrounded by a halo of rainbow-coloured rings of light. This phenomenon was also observed by others and was a subject which was afterwards discussed in a journal. She continued to look at the sun for from five to ten minutes, only shading the eyes occasionally with the hand. On turning away she saw two yellow discs on the grass before her, the one on the right being a complete circle, and that on the left being a circle with a notch in it. The yellow discs became blue when she went into a shaded room and looked at a white table-cloth. These discs had entirely disappeared on the third day, but her vision in both eyes was then impaired. By the seventh day "the sight of her left eye had gone." In a few weeks the right eye had entirely recovered, but two months after the onset of the affection an object still appeared enveloped in a fog when looked at with the left eye alone, and it appeared to have irregular blanks in it. Only slight improvement in the left eye took place subsequently, and she states definitely that so far as she was aware there was no affection of her eyes before the time at which she looked at the sun. When she came under observation at the Royal Ophthalmic Hospital, Moorfields, five months after she first had trouble with her eyes, her vision in the right eye was $\frac{6}{18}$, while with the left she could

Hosted by Google

only see fingers at a distance of three feet. In the left eye also there was a large central scotoma which could not be mapped out. In the centre of this eye white objects could only be seen with difficulty, and red and green were quite invisible. Six years later vision in the right eye with correction was $\frac{6}{9}$; with the left, fingers could be counted at three feet, and there was a well-marked scotoma for red. The left disc was found distinctly pale in colour, but the vessels did not seem to be diminished in size. The vessels and disc in the right eye appeared normal. The chief points of interest in this case are, Mr. Treacher Collins points out, the great defect in vision which resulted and the prolonged exposure to the sun which brought about this great impairment of vision. He also points out that so far as he is aware no instance has been recorded in which atrophy of the optic nerve has followed blinding by exposure to sunlight. Reference is made to the recently recorded experiments of Usher and Dean, in which it was shown that retinal wounds were followed by partial atrophy of the optic nerve. These observers found that degeneration always corresponded to the part of the retina that had been wounded, and that in a monkey's eye, when the lesion was made between the optic disc and yellow spot, the degenerated area lay in the outer part of the nerve anteriorly. Mr. Treacher Collins suggests that in his patient the exposure may have caused destruction of some of the retinal elements in the macular region and consequently atrophy of nerve fibres supplying it. Although there was general pallor of the disc the outer part was decidedly the whiter.

OPENING OF A NEW HOME AT THE CHALFONT EPILEPTIC COLONY.

ON May 6th the foundation-stone of the fourth Home for Epileptics, presented to the National Society for the Employment of Epileptics by Mr. Passmore Edwards, was laid by Mr. Bayard, the retiring Ambassador of the United States. A large company travelled to Chalfont by special train. In addition to Dr. Buzzard, Dr. Ferrier, Dr. Tooth, Dr. Fletcher Beach, Dr. Aldren Turner, and Dr. Colman, who form the medical staff of the colony, many well-known medical men were present, including Sir James Crichton Browne, Dr. Mitchell Bruce, Dr. James Taylor, Dr. Shuttleworth, Dr. Outterson Wood, Mr. Arthur Willis, Dr. Abrahams, and Dr. Brooks. After a brief religious service Mr. Bayard declared the stone to be "fairly and squarely laid," and spoke eloquently on the philanthropic and altruistic spirit which had been such a distinctive characteristic of the Victorian reign. Sir James Crichton Browne, in proposing a vote of thanks to Mr. and Mrs. Bayard, said that it was fitting that Mr. Bayard should take part in this ceremony at an epileptic colony, as he was a distinguished specialist whose province was, by skilful sedative treatment, to avert disastrous convulsions in the body politic. He spoke of the frequency of nervous disorders at the present time, when the "so-called march of civilisation had often a tendency to degenerate into a wild stampede from poverty and hunger." Mr. Passmore Edwards, who was very cordially greeted, spoke of the friendly feeling between this country and the United States, which would render a war between the two countries an impossibility in future. Mrs. Bayard subsequently opened the new Home for Women, the foundation-stone of which was laid by Lord Addington last year. This home will accommodate twenty women, who will be employed in the laundry (which is now being constructed) and in the dairy. Up to the present there has been no resident medical officer, there being no accommodation for one. With the admission of women to the colony, however, the need for adequate supervision of the colony becomes doubled, and it is very satisfactory to learn that Colonel Montefiore has induced an anonymous donor to give £5000 for the erection of a suitable house for a resident physician. It is intended, we believe, that there shall be accommodation in this house for eight or ten patients of a superior class, whose payments on a higher scale will cover the cost of the services of the medical officer to the whole colony. The colony so far has been an unqualified success. Although from the fact that only very severe cases have been taken there have been few "cures," yet in nearly all instances there has been remarkable improvement in the general condition. A glance at the carefully kept market garden and at the large amount of work turned out from the carpenter's shop gave an idea of the useful work which is being done, though there appears room for more variety of occupation, particularly in-door industries, during continued bad weather. Provision of these is, no doubt, only postponed owing to the lack of the necessary funds.

PARALYSIS OF THE FOREARM FROM BICYCLING.

DR. DESTOT has published in the *Gazette des Hôpitaux* an account of his own experiences. An abstract of the paper appears in a recently published number of the *Neurologisches Centralblatt*. After a long ride he experienced paræsthesiæ in the fourth and fifth fingers, with impaired sensibility and paresis in the interossei, lumbricales, and the adductor pollicis. This paresis was followed by distinct atrophy in the affected muscles. He considers the affection to be the result of pressure upon the branches of the ulnar nerve, aggravated, doubtless, by the vibration occasioned by bad roads. He also considers that predisposing factors existed in the softness of the skin of the hand and in the exhaustion of the muscles and the consequent loss of protection to the nerves lying in or under them.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

THE Anatomical Society of Great Britain and Ireland will hold its annual summer meeting at Dublin on June 10th and 11th. In addition to the scientific meetings on each of those days the society will be entertained at the Zoological Gardens in Phœnix Park on one of the afternoons. On the evening of June 10th Dr. James Little, President of the Irish Academy of Medicine, will give a dinner, and on that of June 11th there will be a dinner in Trinity College. Professor His of Leipzig will give an address on the evening of June 9th. After the meetings an excursion will if possible be organised to Killarney. As well as Professor His the following continental anatomists are expected to be present: Professors Merkel, Stieda, Spalteholz, Lebouc, Bardeleben, Van de Stricht, and Disse.

HOSPITAL PROVISION FOR MEDICAL CASES IN CHESTERFIELD.

THE town of Chesterfield has, in common with many other places, been of late considering how it shall most worthily celebrate the completion of the sixtieth year of Her Majesty's reign. We gather from the newspaper reports that three schemes commend themselves to the citizens of Chesterfield—namely: (1) the building of a drill-hall, (2) the building of a medical as opposed to a surgical hospital, and (3) the straightening of the celebrated crooked steeple. At a recent meeting to consider the matter the Mayor is reported as saying that "it would be unfair to have any element of religion about that jubilee gift." Why this should be so we are unable to see, but the drill-hall scheme seemed to be the one which met with the most favour. There is certainly not much religion about a drill-hall, and neither is there about straightening a crooked steeple; in fact, as a rule, church restoration, to quote a well-known saying, is "worse than wicked, it's vulgar;" but there is a good deal of religion about a hospital. In the end

Hosted by Google

it was agreed that the drill-hall should be built, and that any surplus should be devoted towards a fund for the building of a medical hospital. In our opinion provision for medical cases should have been a first charge on the commemoration fund. It is simply absurd that in a town like Chesterfield, with a population of nearly 120,000, there should be no hospital accommodation for medical cases other than the workhouse, and everyone will agree with what Dr. Rose says in his letter, published in another column, that a "man suffering from pneumonia is in more need of hospital treatment than his fellow workman who is admitted for a simple fracture." A hospital, though a work of religion, is at least undenominational in the best sense, and so would meet the Mayor's views, and to our minds it ought to be put in hand at once.

LONDON POST-GRADUATE COURSE.

THE arrangements of the London Post-graduate Course for the summer session, 1897, include lectures and demonstrations on the following subjects:—Diseases of the Skin (on Tuesdays at the Hospital for Diseases of the Skin, Blackfriars); Bacteriology of Anthrax, Tuberculosis, Typhoid Fever, Diphtheria, Erysipelas, &c. (on Fridays at the Bacteriological Laboratory, King's College); Chemistry and Bacteriology of Urine for clinical use (on Thursdays at the British Institute of Preventive Medicine); Clinical Lectures and Demonstrations at the Central London Sick Asylum; Diseases of the Nose and Throat (on Mondays at the London Throat Hospital, Great Portland-street); House Drainage, Water-supply, Infectious Diseases, &c. (on Wednesdays at the Parkes Museum, Margaret-street). A prospectus and any further information may be obtained from the secretary, Dr. J. Fletcher Little, 32, Harley-street, W.

ARSENICAL (?) SOAP.

WE are glad to see that condign justice has at last overtaken not only a retailer but a manufacturer of "arsenical soap." A druggist in Kingston was recently fined in the amount of 10*s.* for selling this stuff, and he, therefore, brought an action against the soap manufacturers for £50 damages. The soap contained no arsenic whatever, and the defence was that "arsenical" was a fancy name, like, say, "Sunlight." We do not call this defence any defence at all. The British public does not really believe that "sunlight" soap contains sunlight, but arsenic is a thing which can be put into soap. The manufacturers' travellers were instructed to say that the soap contained no arsenic, but this does not do away with the incorrect name. "Arsenical" is evidently meant to imply that the soap does contain arsenic. Judge Lushington decided that the druggist had been rightly fined and that the manufacturers were liable for damages. Judgment was accordingly given for £32, a result we are very glad to see. Practices of this kind are far too common and must be suppressed with a firm hand.

THE NATIONAL SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN.

IT is hardly possible that a society operating on a scale which is nothing less than gigantic, and dependent entirely on public subscription, should not at some stage of its history be assailed by the breath of adverse criticism. That stage has been reached by the National Society for the Prevention of Cruelty to Children, and its critic is one of its numerous offspring of local committees. As usual the question in dispute is the management of the society's revenue. The cause of the objecting committee has been espoused by the Charity Organisation Society, and arrangements are in progress for an exhaustive inquiry to be held by Lord Herschell. It would clearly be premature and prejudicial under these circumstances for us or any other outside parties to anticipate the results of that inquiry by a statement of opinion on the merits of the case. We may, however, note as favourable omens the facts that the schism in the society's ranks has not spread beyond the place of its origin; that public confidence in the society, as judged by a marked increase of funds, appears little if at all abated; and that its officials themselves appear rather to court than to shun the pending investigation. It is possible that errors of administration may have crept into so large a scheme of work as that of the society. On this subject we, in common with the public generally, are without information. We may rest assured that any such as may exist will not be overlooked in the approaching inquiry. In the meantime any correct judgment is, of course, impossible, and a truce in the warfare of accusation carried on by the objectors against the society is therefore no more than common sense and good feeling demand.

THE CASE OF MR. R. B. ANDERSON.

A NUMBER of the Fellows and Members of the Royal College of Surgeons of England practising in Plymouth, Devonport, and Stonehouse, and in the neighbouring districts, have addressed a memorial to the President and Council of the College, in which they state that, having observed with a sense of the highest satisfaction the consistent sympathy and moral support which for more than two years have been extended by the College to Mr. R. B. Anderson, they observe with concern that in reply to a resolution of the electorate of the College at the general meeting in 1896 it was stated that the Council did not see its way to vote a sum of money in defence of the rights of a Fellow and Member. Learning also that Mr. Anderson has received no definite reply to his direct application to the College in January last to be protected and defended according to No. 15 of the College By-laws the memorialists desire to lay stress upon the great satisfaction that would be afforded to all Fellows and Members of the College by an active, practical, and consistent defence of Mr. Anderson by a subscription from the collegiate funds to the Civil Rights Defence Committee, and they would like to be heard by way of deputation in support of Mr. Anderson's application.

ASTIGMATISM IN SCHOOL CHILDREN.

A PAPER by Dr. William Carhart in the *New York Medical Journal* of April 17th deals exhaustively with the errors of refraction, especially astigmatism, exhibited by 1000 school children under his observation. The Javal ophthalmometer was used in this investigation, in the course of which astigmatism received particular attention. The age of the children examined varied between five and eighteen years. Few pathological changes were noticed, except those connected with asthenopia, many cases of which were due to mismanagement by ignorant "opticians" of a refractive defect. It is noteworthy that 48·5 per cent. of the children examined were astigmatic and that cases of hypermetropic (44 per cent.) and myopic (3·5 per cent.) astigmatism greatly outnumbered the cases of either hypermetropia or myopia. The low degrees of astigmatism were much more usual than the higher (34·4 per cent. as compared with 10·3 per cent. for moderate and 3·8 per cent. for high degrees). Other tables tend to show that in many cases, especially when aided by a congestive or other morbid process, the undeveloped hypermetropic eye of childhood undergoes a slow distension progressing towards myopia. In such cases emmetropia, which is shown to be most common in the middle part of the school period (from nine to twelve years of age), is merely a stage on the road which leads to myopia. Hypermetropia also shows a tendency to decrease rapidly in consequence of alteration of the corneal

Hosted by Google

curve developing compound hypermetropic astigmatism. The myopic analogue of this condition, where present, develops later. The conclusions at which Dr. Carhart arrives are, (1) that changes in refraction in childhood and adolescence are due to slow distension of the eyeball, either by ocular strain in the healthy eye or by ordinary physiological use of an eye weakened by disease; (2) that such distension is accompanied by change in the corneal curve; (3) that many cases of hypermetropia, and all of myopic and mixed astigmatism, are thus explained; and (4) that consequently early correction of the refractive error and especially of the astigmatic element is of great preventive value. The paper contains practical suggestions as to the prevalence of visual defects in childhood and the necessity for their treatment which parents and school teachers will do well to note and act upon.

A HOME FOR CONVALESCENTS FROM SCARLET FEVER.

IT is generally recognised that the infective stage of scarlet fever continues for several weeks, and that the mere fact of a convalescent feeling himself to be in good health and fit for any kind of out-door exercise is no guarantee that he may safely mingle with the public at large. The requisite long-continued isolation being extremely difficult under the ordinary conditions of family life, Miss Mary Wardell in 1884 opened a home for convalescents from scarlet fever at Brockley-hill, Stanmore, Middlesex, and from that date to the present time 2663 patients have been received. During 1896 there were 273 admissions, classified according to age as follows: seven years old and under, 72; twelve years old and under, 74; twenty years old and under, 42; and above twenty years old, 85. On May 17th, at 3 45 P.M., a meeting will be held at Grosvenor House, by permission of the Duke of Westminster, its object being to give some account of the work done during the last twelve years, and to raise a sum of £2000 which is required to clear the home from all debt and to provide for the carrying out of some very necessary repairs.

THE POOR-LAW OFFICERS SUPERANNUATION ACT AT WISBECH.

THE Wisbech board of guardians have evidently been slow to realise the scope and intention of the Poor-law Officers Superannuation Act. At their meeting held in the middle of last month, a letter was read from Mr. William Groom, medical officer and public vaccinator, in which he tendered his resignation, mentioning at the same time that it was more than forty years since the board appointed him deputy to his predecessor, and that he had been medical officer for thirty-seven years. Thereupon, according to the *Wisbech Advertiser* of April 14th, the chairman (the Rev. J. Young), addressing the guardians, said that this resignation "meant £70 per annum in superannuation. They were legally bound to pay it, and had no alternative. As he had told them some time ago, it was never anticipated that Dr. Groom or any other medical officer would come under the superannuation scheme. With regard to the officers who had been established in the Union House for a number of years it was quite a different matter. The outside officers had never anticipated or thought of superannuation, and it seemed very hard upon the ratepayers that in such cases they should have to pay it. The only alteration he could suggest, and he made it without hesitation, was that they should not give the same salary, but considerably reduce it. The present salary was £105, being £80 for Wisbech, £10 for Wisbech St. Mary, and £15 for Leverington. He would suggest that the salary for Wisbech be £50, making £75 in all." Mr. Howard seconded the proposition. The position taken up by the reverend gentleman is obviously open to a good deal of criticism, and any candidate for the vacancy who may be willing to accept the greatly reduced salary should keep in mind that it is subject to a statutory deduction on account of the superannuation grant in question.

THE INTERNATIONAL MEDICAL CONGRESS AT MOSCOW.

THE following is a convenient route for medical men from Scotland intending to be present at the International Medical Congress at Moscow. Leaving Leith by one of Messrs. James Currie and Company's steamers, Hamburg is reached about forty hours later, and the train can be taken at once to Berlin. Here a day or two might be spent, and the journey then continued to Moscow. After the Congress has finished its sittings the return journey might be taken by the same route. It would be more interesting, however, to vary it by returning by St. Petersburg, Stockholm, and Copenhagen, from which latter place a steamer leaves every Thursday for Leith. A return ticket should be taken on the Hamburg steamer; this is available from Copenhagen on payment of one guinea. The total cost of this tour would be £18 6*s*. 10*d*. if travelling first class by rail, or £14 19*s*. 2*d*. second class. To this have to be added, say, 12*s*. per day while on shore for board and lodging; the fares on the steamers mentioned include provisions. Instead of travelling by railway from Stockholm to Copenhagen the following alternatives are available: (1) by canal to Gothenburg and by steamer to Copenhagen; (2) by canal to Gothenburg, by steamer to Christiania, and thence by steamer to Christiansand; and (3) by railway to Christiania and by steamer to Christiansand. The additional cost would be £1 0*s*. 2*d*., £2 1*s*. 11*d*., and 11*s*. 4*d*. respectively.

THE PLAGUE IN BOMBAY.

THERE is nothing very new to report about the plague, except that the spread of the disease is slowly diminishing owing to the Government some two months ago having at last made up its mind to enforce the regulations for isolation and segregation which it instituted at the end of last year and then allowed the municipality to disregard. Native medical men are badly wanted, for the native patient will not allow himself to be attended by a European, but the supply of nurses is ample. Yersin's serum treatment is apparently not successful, the mortality in a series of selected cases—i.e., cases inoculated within forty-eight hours of attack—being about 50 per cent., the same as the hospital mortality. In one case, although the symptoms due to the plague abated after the inoculation, cardiac failure supervened, and the patient died. It will be remembered that a somewhat similar coincidence has been reported as following the injection of diphtheria antitoxin. If, however, the appalling mortality and the loss of trade which Bombay has experienced lead to a reconstruction of the insanitary tenement houses and impress on the authorities, both municipal and imperial, that disease is not to be trifled with, that if not met and fought with at the very outset it will some day slay its ten thousands, the lesson of the present epidemic, though a bitter one to learn, will not have been altogether useless.

THE REMOVAL OF EMBEDDED POWDER GRAINS.

DR. EDWARD JACKSON, of Philadelphia, contributes a very useful paper on this subject.[1] On the face the operation is of most importance in consequence of the disfigurement. If any grains are situated superficially a good deal of spontaneous improvement will occur, as they will be thrown

[1] Albany Medical Annals, May, 1897.

Hosted by Google

off with the epithelium. To favour this poulticing or blistering may be tried. But the deeper particles will not be affected. At first they are massed in small areas which give the appearance of black grains capable of removal singly. But even at this stage they are so incorporated with the tissues that this is impossible. A recognition of this fact will save the patient unnecessary pain and the surgeon disappointment. The problem is really the removal of the tissue in which they are diffused with the least possible destruction. After failure of many methods Dr. Jackson used a fine-pointed galvano-cautery, with which he destroys each spot. The earlier it is applied the less is the tissue which has to be destroyed, for as time goes on the stain becomes diffused In old cases where the whole skin of the part is involved the method cannot be employed. As repeated applications are often necessary (in one case he made 300 at a single sitting) an anæsthetic is required. Ether is inadmissible, therefore he uses chloroform. Where the number of grains is small, local anæsthesia in the form of Schleich's infiltration method may be employed. The tip of the cautery at a white heat is quickly introduced to the necessary depth and quickly withdrawn. In severe cases it is impossible to judge correctly the depth, so that repetition may be necessary. For grains embedded in the cornea the operation is precisely that of cauterising for ulcer.

THIRTY-FIRST ANNUAL REPORT OF THE CITY OF LONDON LUNATIC ASYLUM, STONE, NEAR DARTFORD, 1896.

THE history of this institution during the past year has been uneventful. One hundred and thirteen patients were admitted, forty-six recovered, and twenty-three died; one-half of the admissions were acute and recent cases of insanity. The percentages, both for recoveries and deaths, compare very favourably with the latest average returns of the English county and borough asylums. In commenting upon the fact that only one death was due to pulmonary phthisis, Dr. White points out that this disease is a rare cause of death at the Dartford Asylum. Phthisis, as a rule, figures largely in the mortality tables of lunatic asylums, and its comparative infrequency at the City of London Asylum must be regarded as a satisfactory feature. Heredity and alcoholic intemperance figure as the most potent causes of insanity. The department for paying patients continues to meet with deserved success, and there can be no doubt that this asylum in providing accommodation for private patients at a moderate rate of board is engaged in doing good work. The high recovery-rate, the low death-rate, and the remarkable freedom from casualties of a serious nature all tend to show that the institution is ably and carefully managed.

THE Eighth International Congress of Pharmacy will be held at Brussels from Aug. 14th to 19th inclusive. The proceedings of the Congress are designed to interest all working in pharmacy or such allied branches of knowledge as toxicology, pharmaceutical chemistry, bacteriology in relation to pharmacy, and the legal position of the dispenser and the prescribing physician. There will be prizes given for essays contributing to scientific or practical knowledge on any of these points. All information can be obtained from the secretary-general, M. Duyk, 102, Chaussée de Wavre, Ixelles, Bruxelles, Belge.

HER ROYAL HIGHNESS PRINCESS CHRISTIAN will present certificates of appointment and badges to the members of the Army Nursing Service Reserve at the Royal United Service Institution, Whitehall, on Wednesday, May 19th, at 5 P.M. The Marquis of Lansdowne, Secretary of State for War, will preside.

THE examination of the Medico-Psychological Association of Great Britain and Ireland for the certificate of Psychological Medicine will be held in London, Edinburgh, Glasgow, Aberdeen, and Dublin in July, upon dates which we shall notify in due course. The examination for the Gaskell Prize will be held in London in July, and is open to all who possess the certificate of the association. Candidates intending to present themselves should give at least fourteen days' notice to the Registrar, Dr. Spence, Burntwood Asylum, near Lichfield, to whom all inquiries should be addressed.

SURGEON-MAJOR-GENERAL JOHN BY COLE READE has been appointed a Knight of Grace of the Grand Priory of the Order of the Hospital of St. John of Jerusalem in England, and George Sampson Elliston, M.R.C.S. Eng., and Christopher Childs, M.D. Oxon., have been promoted from Honorary Associates of the Order to the same dignity. Deputy-Surgeon-General George Sterling Ryerson, M.D., has been promoted from Honorary Associate to the dignity of an Esquire.

THE annual meeting and May dinner of the Aberdeen University Club, London, will be held at the Holborn Restaurant on Wednesday, May 19th, at 7 P.M. Mr. John W. Crombie, M.P., will take the chair, and intending diners should communicate with the honorary secretaries, Mr. J. Gerard Laing and Dr. James Galloway, at 54, Harley-street, W.

THE vacancies on the staff of the Middlesex Hospital caused by the death of Mr. Leopold Hudson were filled up at a meeting of the election committee, held on Wednesday last, when Mr. T. H. Kellock, F.R.C.S. Eng., was appointed assistant surgeon, and Mr. Stephen Paget, F.R.C.S. Eng., surgeon to the Throat and Ear Department.

DR. WILLIAM ALLEN STURGE of Nice has been appointed by the Queen to be a Member of the Fourth Class of the Royal Victorian Order, which was instituted last year with the object of recognising personal services to Her Majesty.

THE meeting of the Hospital Reform Association announced to be held at Manchester on May 24th will be held on May 25th instead.

HIS ROYAL HIGHNESS THE PRINCE OF WALES has fixed Wednesday, May 26th, as the date of his visit to Guy's Hospital to open the new medical school buildings.

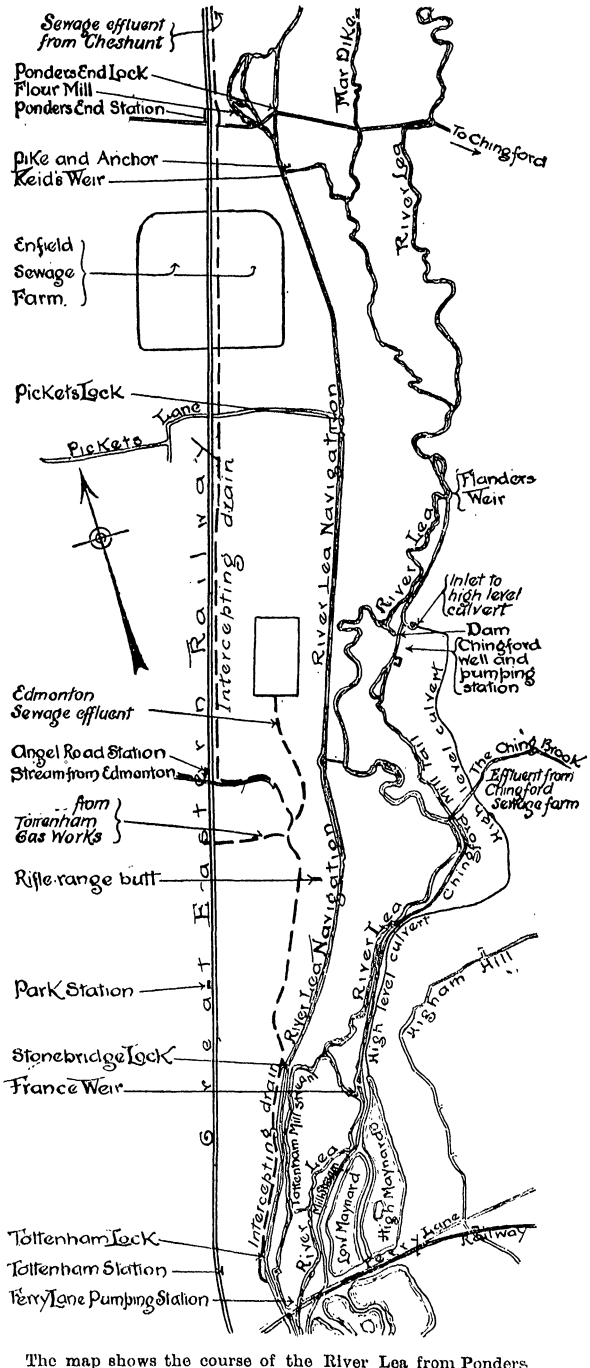
THE QUEEN has forwarded through Sir Fleetwood Edwards her annual subscription of £105 to the funds of the Middlesex Hospital.

THE next session of the General Medical Council will commence on Tuesday, May 25th, 1897.

THE SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.—The annual report of this institution, which has lately been issued, shows that during 1896 1211 in-patients were admitted, being 59 in excess of the previous year. 2660 out-patients were treated, as against 2274 in 1895. The average stay of each patient was 31·79 days, and the total average cost was £5 0*s.* 1¼*d.* per patient, or 3*s.* 1¾*d.* per day. The average number of daily occupied beds was 105·42. The total expenditure for 1896 amounted to £6128 10*s.* 10*d.* The treasurer states that although during the past year the income exceeded the expenditure by £6, yet there is still outstanding against the hospital a deficit of £200 18*s.*, the adverse balance of the previous year, and also the sum of £465 1*s.* 7*d.*, the cost of improving the operating theatre in 1895.

Hosted by Google

The Lancet Special Commission ON THE METROPOLITAN WATER-SUPPLY.



XII.[1]

EAST LONDON WATERWORKS COMPANY (*Continued*).

Water from the Lea.—The greater part of the water supplied by the East London Waterworks Company is taken from the river Lea. The rights which the company possess of taking water from the Lea are somewhat peculiar. The Lea Conservancy Board is empowered to use as much of the river Lea water as is necessary for filling the locks for the use of the barges which pass up and down the Lea Conservancy stream, and the New River Company and the East London Waterworks Company are allowed to take the whole of the water which is in excess of that used for purposes of navigation.

From a very early period the Lea has suffered very much from pollution by sewage and surface drainage. In the year 1852 an Act was passed to enable the East London Waterworks Company to make an artificial cut to intercept some of the sewage, which up to that time, had contaminated the intake of the Company. This intercepting drain will be first described, and then an account will be given of the sources of the water which is taken at Chingford for the supply of the reservoirs of the Company.

The Ponders End intercepting drain.—The accompanying map shows the course of the drain, which is marked by a dotted line. The map is drawn to scale, but the two sewage farms which are shown are diagrammatically represented. The drain passes from Ponders End through the valley to a point in the Lea Navigation Canal which is just below the Tottenham Lock, a distance of about four miles. It was provided by an Act of Parliament that the East London Waterworks Company should be at the expense of keeping up this intercepting canal. At the present time, therefore, the East London Waterworks Company differs from all the companies which have been previously described in the fact that the Company has at its own expense to keep up an intercepting drain made to prevent the pollution of the water which is taken by the Company. And this drain forms part of the property of the Company. The cut begins at a point within a few yards of the Ponders End railway station on the Great Eastern Railway line. The intercepting drain first receives the effluent of the sewage farm of the Cheshunt Urban District Council, and it receives near this point some drains which carry surface water down. The amount of water passing down varies very much. After a very heavy rain it is estimated that as much as 4 000,000 gallons a day may be conveyed. When visited on May 6th, about midday, the amount at the commencement of the cut was very small and consisted entirely of the sewage effluent from the Cheshunt district sewage farm, and the flow was roughly estimated as being at the rate of about 750,000 gallons a day. The amount, however, which passes from the sewage effluent of course varies at different times in the day. On May 6th this sewage effluent was very foul. There was a great quantity of solid matter in suspension. Just before the effluent flows into the ditch there is an arrangement put up by the Cheshunt urban authorities by which the effluent passes through four wire gratings, which remove a good deal of the solid matter. A man is employed to constantly remove the débris and cleanse the gratings. A considerable amount of solid matter is, however, allowed to pass through into the ditch. The intercepting drain passes in a southerly course near the Great Eastern Railway line for a distance of about half a mile, when it receives the effluent of the sewage farm of the Enfield sanitary authority. On May 6th this effluent was turbid and extremely foul. The ditch continues in a southerly course,[1] close to the Great Eastern Railway, and passes under a public road called Picket's-lane close to the signal-box of that name on the railway. The smell at Picket's-lane was, on May 6th, very offensive. At this point, and at several others in the course of the ditch, it receives surface-water drains which brings the flood water from the higher ground on the west side of the line. At Angel-road the drain passes under the public high road and takes a turn to the east. At this point it receives a stream called Pymme's brook from Edmonton. Having gone in an easterly direction for about 200 yards the drain again takes a southerly course. About half a mile further the ditch receives the sewage effluent of the Edmonton sewage farm, the position of which is diagrammatically given in the

The map shows the course of the River Lea from Ponders End to Ferry-lane, the intakes of the East London Water Company at Chingford, the course of the aqueducts which convey the water to the reservoirs of the Company, and the intercepting drain which receives various sewage effluents and prevents them from contaminating the Lea above the intake of the Company. The map is drawn to scale with the exception of the Enfield and Edmonton Sewage Farm.

[1] Nos. I., II., III., IV., V., VI., VII., VIII., IX., X., and XI. were published in THE LANCET of Feb. 20th and 27th, March 6th, 13th, 20th, and 27th, April 3rd, 17th, 24th, May 1st, and 8th, 1897, respectively.

Hosted by Google

map. This effluent on May 6th contained extremely foul smelling, dark-coloured stuff. The point at which the effluent reaches the drain is nearly a mile from the sewage farm, but in spite of the fact that this effluent had been flowing for that distance through an open ditch it was still extremely foul, although it must have deposited a considerable amount of its feculence in its passage through so long a course. A little further on there is an open ditch which flows in from the direction of the Tottenham and Edmonton Gasworks. A little south of this point the drain passes close to the Stone Bridge lock; and about 200 yards south of this point it receives a stream named Carbuncle ditch which flows from Tottenham. The ditch continues its course just to the west of the River Lea Navigation Canal, passes under the road close to Tottenham Lock, and is conducted through four stone arches for a distance of about 120 yards, when it discharges itself into the Lea Navigation Canal just below the Tottenham Lock. The ditch from the beginning to the end is a foul open sewer. The East London Waterworks Company have no direct authority over the sanitary authorities who discharge their sewage effluents into the stream. The control of this matter is in the hands of the Lea Conservancy Board. The duty of the East London Waterworks Company is to keep the ditch clear. The work that is actually done is that in the spring or early summer, and again in the autumn, about six men are employed to clear out the course of the stream "from below upwards," if it be permissible to employ an expression rendered classical by the late Mr. Gray. The work takes about five or six weeks, and the way in which the grass grows on the banks of the ditch bears witness to the high manurial value of the matter removed from the drain.

Course of the water to the Chingford intake.—The water which is taken at Chingford by the East London Waterworks Company comes by more than one channel. This will be seen by a glance at the map (p. 1359). From Chingford to Ponders End the road crosses the River Lea, Mar Dyke, the River Lea Navigation Canal, and Ponders End Mill tail. Water from all these sources passes to the intake at Chingford. Some water comes down the River Lea Navigation Canal Cut from Ponders End Lock and some by the flour mills which are situated at Ponders End, and the water passes just to the west of a public house called the Pike and Anchor. Here on the east side of the Lea Navigation Cut there is a sluice (Keid's weir). From this point to the reservoirs the East London Waterworks Company takes charge of the bed of the stream. A short distance from the Keid's weir the stream is joined by the stream or ditch called Mar Dyke, it then proceeds in a southerly direction for about a mile, when it is joined by the River Lea, which here runs in its ancient course from a point not far from Waltham Abbey. Roughly speaking, half the water comes down this old course of the River Lea and Mar Dyke and half from the Lea Navigation Cut near the Pike and Anchor. Over the River Lea, down which about half the water comes, the East London Waterworks Company have no authority. From the point of junction of the Lea and the cut from the Pike and Anchor the stream flows in a more or less southerly direction to Chingford Mill. In the latter part of its course, below Flander's Weir, the water is conveyed through an artificial cut, and the surplus water, if there be any, and the rest flows over the weir into the natural course of the old River Lea. The weir is kept up by the Lea Valley Drainage Commissioners. During the flood time a considerable amount of water flows over at this point. During the summer the whole of the water is taken by the East London Waterworks Company. The water is conveyed to the station at Chingford, from whence it proceeds in two separate channels, a high-level culvert which supplies the high-level reservoirs and an open stream which was formerly the mill tail of the Chingford Mill. These aqueducts must be separately described.

Chingford (See G on Map, THE LANCET, May 8th, p. 1291).—At Chingford there is a deep well; the upper part of it is brick and the lower part is lined with 10-ft. iron cylinders. The depth of the well is 200 ft. At the bottom of the well there is a heading which passes in a northerly and southerly direction for a distance of about 200 ft. From this well water is pumped (1) to the low level aqueduct, by which it is conveyed to Walthamstow; (2) to Buckhurst-hill reservoir. Buckhurst-hill is entirely supplied from this well. There is a second well 60 ft. in depth. This is lined with iron cylinders for about 15 ft., and the lower part is brick. It is from the bottom of this that the bore hole goes down to a depth of 451 ft. from the surface. The width of the bore hole is 2 ft. From this well water is pumped by turbines; it all goes to Backhurst-hill.

Engine-house.—There is a quadruple expansion engine which has cylinders with the respective diameters of 12 in., 17 in., 24 in., and 30 in. The stroke is 2 ft. 6 in. The engine works two cranks which are keeled at right angles to each other. It works two pumps, of which the buckets are 21 in. in diameter. The disc to which the bell cranks are fixed is so arranged that the crank can be put in any one of three positions. The stroke is thus regulated. During the week ending May 1st an average amount of half a million of gallons daily was pumped. The steam for working the engines is generated by two Lancashire boilers, which are provided with a feeding conveyor and automatic stoker. This is worked by a small engine.

Turbines.—The turbines are situated in a house close to the stream, and the fall which was formerly used for the Chingford Corn Mills works them. These turbines pump water from the well last described to Buckhurst-hill. They pump also water which is raised from the other well by a steam engine which has been described. The engine-house is light in structure and possesses a tower fitted with a sliding roof. This arrangement makes it possible to remove the well rods without trouble. There are two cottages at this station. This station is in telegraphic communication with Walthamstow and with Lea Bridge.

(To be continued.)

THE SANITARY CONVENTION OF VENICE, 1897.

No. II.[1]

ONE of the first important acts of the British Government at the Venice Conference was to announce that they had decided to ratify the Paris Convention subject to three conditions. They maintained their refusal to assent to the quarantine restrictions concerning the traffic in the Persian Gulf; they declined to assent to the requirement as to the possession by every pilgrim of means to cover his journey to and from the Hedjaz except and until the local circumstances should admit of this; but they consented to raise the surface per pilgrim on the main deck to 16 square feet, instead of the 12 square feet which is at present required under the existing Indian Regulations. The second important step was to announce through their delegates that the pilgrimage from British India had been entirely prohibited for this year. These two announcements met with a most favourable reception, and they probably had a distinct influence in leading the conference to adopt conclusions more favourable to British views than any heretofore embodied in any international sanitary convention. The consistent attitude maintained by this country as to the Persian Gulf must also be credited with the more advanced conclusions assented to as to traffic up the Gulf for the purposes of the control of plague than those which form part of the Paris Convention.

These conclusions, as also those relating to the traffic through the Suez Canal into the Mediterranean are on lines which call for special notice. Hitherto all conventions have been based on the requirement that entrance into the Shat-el-Arab at the head of the Persian Gulf, and into the Suez Canal, shall be preceeded by a voyage, after leaving an infected port, which shall be of sufficient duration to cover the period of incubation of the disease to be controlled. Five days had been decided on for the purposes of cholera; but the application of the same principle to the ten days period of incubation deemed necessary in the case of plague, would have meant detentions of a most serious and costly character for all vessels sailing from Bombay and Kurachee both at the mouth of the Shat-el-Arab and above all at the entrance of the Suez Canal. Indeed all healthy vessels would have been compelled to lie idle for a period of from three to four days merely to complete these ten days, and this on a mere assumption that perhaps someone on board might be incubating the disease. The British delegates were successful in combating the need for any such action,

[1] No. I. was published in THE LANCET of May 1st, 1897.

Hosted by Google

and they secured the passage of the canal and of the Shat-el-Arab "in quarantine," that is to say with guards on board to prevent communication with the shores of these comparatively narrow sea channels. This will enable healthy vessels to ascend directly up to Bassorah, the commercial capital of lower Mesopotamia, and directly into the Mediterranean without any quarantine detention. The gain is a very great one; and its acceptance will secure the free admission of all such vessels into any port as soon as the ten days are completed. In the case of vessels leaving Bombay for Europe this period will, in all cases be completed before Brindisi is reached, and the presence of a medical officer and of means of disinfection on board will relieve the vessel from all restrictions. All our Indian passenger ships and troopships have a medical officer on board; and, with steam always available, it ought to be a very simple matter to arrange also for the provision of adequate means of disinfection. It is further provided in the Convention that if plague has occurred on board vessels not provided with a medical officer, they shall be accorded the same freedom of passage as soon as twelve days have elapsed since the last case; and even in the case of vessels actually infected with the disease, but having a medical officer on board, they may likewise pass on at once "in quarantine" provided they land the sick and those who have been in actual contact with them.

An example of the working of these new rules occurred a few days after the Convention was signed. The Indian troopship *Dilwara* had a fatal case of plague on board, and the body having been buried in the Red Sea, the only requirement before the passage of the Suez Canal in quarantine was accorded, was the disembarkation at the hospital at Moses's Wells of the father and mother of the patient, who had acted as sick attendants, and the disinfection of that part of the vessel occupied by the patient. Had the Convention not been signed, it would have been competent for the Maritime and Sanitary Board of Egypt to have required the landing of all the 1,235 persons on board or their detention until twelve days had elapsed since the burial of the body before they could have entered the canal. The cost of this, and the grave inconvenience it would have caused, would probably have ended in the troopship returning down the Red Sea, and sailing for Southampton by the Cape Route.

Continuing our account of the maritime regulations, in so far as they relate to arrivals in European ports, we again find a great advance on previous Conventions. Under the guise of the maintenance of a so-called "period of observation" the most stringent quarantine is still permissible, though not obligatory, in the case of cholera under the Dresden Convention; but England's ratification of that Convention was dependent on the condition that we would not, in our ports, detain people in quarantine who were healthy, even though we were asked to do so because a new name had been given to the detention. This attitude probably led to a very important change in the recent Venice Convention. It is true that, as regards actually infected vessels, detention "in observation", otherwise in quarantine, for ten days is still permissible; but for other vessels, and notably those which have recently sailed from an infected port but which have thus far had no plague on board, the Convention only allows "supervision" for a sufficient term of days to complete the ten days incubation period since the vessel sailed from the last infected port; and this supervision is clearly defined as meaning that, whilst all persons are to be allowed at once to land, supervision shall only be maintained over them at the residences to which they may choose to go in the country of arrival. In other words the English practice, which has so long been adopted with regard to cholera, and which came into operation as regards plague last year, has been accepted for suspected vessels by such of the European and other countries as have signed the Convention of Venice. This is a very striking result; it was secured at the time when panic-stricken regulations of the most absurd and trivial character were being imposed at southern ports of Europe; and it is generally admitted that the adoption of our reasonable and sufficient regulations was in the main due to the record of the success attained in this country which was expounded by the British delegates, and to the conviction which came home to many of the delegates that the English system was the only one which could give to the inhabitants of any country a real sense of security, and thus prevent the occurrence of panic where there was absolutely no need for any such exaggerated fears as had been expressed. To give an example of the application of this principle, we may once again refer to the case of the *Dilwara*. She arrived at Southampton on April 6th, with a record of fatal plague. All the 1,200 people on board were medically examined, they were found free from plague; the troops were conveyed to their barracks, &c., and the discharged soldiers with their wives and children were free to go to their homes. But the addresses of all were known, and the local health officers or military surgeons were advised as to the necessity of watching them for a few days in their own residences. As to the vessel, a few extra precautions were taken as to the part of the vessel occupied by the sick, and disinfection of certain suspected articles was carried out, after which the vessel was at once berthed in dock.

It is notorious that the adoption by the Conference of these modern and reasonable views was to a considerable extent due to the support which the British delegates received from other delegations, notably the French and the Dutch. On this subject we would call attention to an able statement made by Professor Brouardel in the *Journal Officiel de la République Française* of April 8th. The distinguished professor, whose advanced and liberal views are much ahead of those of some of his countrymen, notably those of southern France, announces that England can with some impunity act, as regards imported diseases, on her principal of avoiding restrictions, because of the pecuniary sacrifices which we have accepted in order to place our country in a condition to resist the spread of any chance infections from without. We acknowledge the courtesy of Professor Brouardel in this matter. But where he seems to imply that similar action may not be possible for other countries because their peoples cannot imitate us in our expenditure, we think that some fallacy underlies this view. We adopted this attitude some fifty years ago; that is to say a generation before we had commenced our systematic heavy expenses and public health improvements; and it was because the English people knew that they would not, even if they could, be protected by quarantine restrictions, that they set themselves to work and to pay for the improvements in the sanitary condition of their towns and villages. Had we pretended to afford protection by quarantine, pending the adoption of sanitary measures, we should have failed to secure these improvements; and we cannot too strongly urge on other countries that the pretence to prevent disease entering a country by quarantine restrictions gives the people of that country a ready and a perfectly reasonable excuse for avoiding expenditure in promoting public health measures. Happily we know that France does not, officially at least, adopt any such line of argument; and under the advice of a number of the most eminent members, including the president, Mons. Brouardel, of the Comité Consultatif d'Hygiène Publique, that country is doing much to put sanitation first, and to avoid needless restrictions on the movement of vessels and of persons. The French delegation were admittedly prominent amongst the supporters of this modern system at the Conference which recently assembled at Venice.

THE PRINCE OF WALES'S HOSPITAL FUND.

THE TOTAL OF CONTRIBUTIONS.

THE Prince of Wales's Hospital Fund had received up to Wednesday last £76,805 13*s.* 9*d.* in donations, £18,401 14*s.* 3*d.* in annual subscriptions, and £19,133 12*s.* in commuted subscription.

THE ISSUE OF STAMPS.

The Jubilee Stamps issued for the benefit of this Fund will be on sale to the public on Tuesday next, May 18th. They are issued to give small subscribers a handy and convenient form of receipt and one which they can retain as a memento of the Diamond Jubilee and of that increasing interest in hospital support and management shown during Her Majesty's reign, not only by the Royal Family, but by all classes throughout the country, and culminating in this effort to set the hospitals of London on a sound financial basis. It is also evident that stamp collectors are largely interested,

Hosted by Google

and spaces for these stamps are being made in many new albums, in addition to the issue of specially prepared pages for insertion in existing albums. The basis of the design selected by the Prince of Wales is taken from no less an authority in art than Sir Joshua Reynolds, whose well-

The shilling stamp, reproduced in black and white, and enlarged by one-third to show the details. The colour of the shilling stamp is indigo blue, and that of the half-crown stamp, which is identical in design, is Venetian red.

known picture of "Charity," executed for one of the Virtues, in New College Chapel, Oxford, is the most appropriate design that could have been selected, embodying as it does a beautiful picture with Mrs. Sheridan as the chief figure.

Valuable assistance has been rendered by Mr. De la Rue and by Mr. Purcell, C.B., the Controller of Stamps at Somerset House, who have taken the greatest interest in the undertaking from its commencement.

After His Royal Highness had approved of the design the engraving was begun and proved a very much more serious affair than any one unversed in these details would have anticipated. Such an engraving could only be executed by the most skilled hand. After the matrix had been produced and hardened it had to be rolled into the steel plate under a pressure of twenty tons given by a lever set in motion by the foot of the operator, and each impression had to be rolled in separately, the greatest care being taken to adjust the proper distances and a magnifying glass being constantly in use. Each plate contains a double sheet of eighty, in which one false impression would spoil the whole, and great liability to cracking arises from the weight of the pressure. Every sheet has to be accounted for as carefully as a bank-note, and this again entails still greater surveillance.

It is needless to say that the fact of His Royal Highness the Duke of York being President of the Philatelic Society insures the greatest interest being taken in these stamps by collectors in all portions of the globe, and as a work of art there will be nothing wanting in them. A large quantity of the issue has already been secured for insertion in the Queen's Commemoration Bible and also in the Queen's Commemoration Prayer and Hymn Book, which are to be published as soon as the stamps are ready, and each of which will contain a stamp; we are informed by the publisher that the greatest interest has been shown all over the country, inquiries having arrived from many places abroad and telegraphic orders having been received even from South Africa.

His Royal Highness the President of the Fund has graciously signified that he will, if possible, personally witness the destruction of the plates from which the stamps are printed; but in any case they will be destroyed as soon as the printing of the limited number of the issue is completed in the presence of the official representatives of the Fund, and of Mr. Purcell, C.B., Controller of Stamps. A certificate to this effect will be duly published in accordance with the usual regulations.

Our readers will remember that in the case of the Rowland Hill Postcard in 1890 so great was the demand that the value of the postcard advanced no less than 2500 per cent.

The trade will be supplied by Messrs. Simpkin, Marshall, Hamilton, Kent, and Co., Limited, Stationers' Hall-court, London, E.C., and the stamps can be obtained from all stationers and booksellers with the exception of railway bookstalls.

THE GRECO-TURKISH WAR.

THAT which most people, and especially all military people, foresaw has come to pass. Greece, in rejecting the advice of the European powers and the counsel of all her real friends, and in yielding to the popular clamour of her own population backed by the irresponsible support of others outside her own territory, has done herself as a nation great, and it may be irretrievable, injury. Neither in the extent of her population, the character and strength of her army, the ability and enterprise of her generals, nor in her preparedness for war, was she ever really equal to the work she took in hand. Her action has had exactly the reverse effect of that she intended, for Greece has rehabilitated the political power and influence of Turkey to her own grave injury and to the prejudice of civilisation and good government in Europe generally. The Greek navy, of which so much was expected, has done nothing; the Greek army is threatened with immediate dissolution. None of the engagements that have taken place have really been battles, and it is no doubt a very good thing for Greece that no pitched battle on a large scale occurred. The Turks are known to be splendid soldiers in grit and quality — resolute and brave, patient and temperate, possessed of a fine physique, amenable to discipline, and always exhibiting, when called upon, great powers of physical endurance. It seems clear that the order had gone forth on this occasion to the Turkish army that there were to be no massacres, that the eyes of Europe were upon them, and that a punctilious regard was to be paid to the rules of civilised warfare. The consequence has been that the discipline and moderation of the Turk in the present war has been made known and manifested to all men. From all sides it has been reported that their conduct in this campaign has been admirable. The trained and disciplined Greek troops have, by all accounts fought well, but their army was to too great an extent made up of excitable and unreliable bodies of men, and wanted cohesion. They were both outnumbered and outgeneralled, and, disheartened by want of success, they seem to have more readily given way to panic than better trained and disciplined troops would have done. It is no longer a question of the realisation of Greek aspirations, for Greece has already had to relinquish the avowed object of her rash enterprise. The feeling of the Christian nations is one of pity and regret for all the misery and misfortunes which she has brought on herself, and Greece has now to appeal to the European Powers, whose advice she previously rejected, to intervene in her behalf.

The Turks have not only spared no pains to improve their whole military system and to bring their army up to the standard of modern warfare, but they have also taken great care to render their hospital service efficient in the field. According to all accounts their hospitals have been well provided for and managed, and the sick and wounded have been well looked after. In addition to their regularly-established hospitals and ambulance transport they have received a good deal of aid from outside sources. The Czar has informed the Sultan of the despatch of an ambulance, with surgeons and nurses for 500 beds and all requisites. The Turks do not appear to have suffered so much from exposure and climate as their opponents, and the amount of sickness among them is not large. The Greek troops who took part in the fighting at Velestino have suffered greatly from the almost tropical heat during the day and the cold nights The hospital at Lamia is full of sick. According to the *Times* correspondent the Greek casualties in the Epirus army during the campaign have been about 500; of this number 180 were killed and missing in the last Pentapigadia fight. Of the losses that occurred in and about Pharsala and in the retreats from Larissa, Pentepigardia, and Pharsala we know very little at present. The town of Arta, which is crowded with troops and refugees, is reported to be in a most insanitary state and is becoming very unhealthy. Typhoid fever and dysentery have broken out and threaten to become epidemic. The climatic conditions of the hills commanding the plain of

Hosted by Google

Pharsala are very severe: great heat, followed by unusual cold and heavy rains, drenching the unsheltered lines. Several men of the Foreign Legion, the *Times* correspondent states, are suffering from dysentery. Supplies are sufficient in quantity, but consist of only mutton and bread from Lamia. The commissariat, transport, and medical service at Domoko are inadequate, and there is a want of stretchers and ambulance for the transport of the wounded. There is said to be a good deal of sickness among the troops. Efforts are being made by English agencies for procuring medical stores from Athens and for making temporary hospital arrangements. Happily there is every reason to hope now that peace will be established, and that there will be an end to this very lamentable and unequal contest.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Portsmouth Urban Sanitary District.—In the annual report for the borough of Portsmouth for 1895 we have the last report made by Dr. Mumby in his capacity of medical officer of health. The population of Portsmouth in the middle of 1895 was estimated at 174,751, the mean density of the population being 39·1 persons per acre; the density, however, varies very materially in different parts of the borough. The corrected death-rate of Portsmouth during 1895 was 18·2 per 1000, a rate which placed Portsmouth in the position of possessing the lowest death-rate but one amongst the thirty-three large towns. In regard to the specific infectious diseases it is gratifying to learn that diphtheria is decreasing both in prevalence and severity in Portsmouth, and Dr. Mumby furnished a table showing that during the years in which notification has been in force the notifiable diseases have markedly decreased, while the non-notifiable diseases have hardly diminished at all. In an appendix to the report Dr. Mumby has bequeathed, as it were, a sort of legacy to Portsmouth in the shape of life tables for the borough based upon the figures for the years 1881 to 1890. The compilation of these tables must obviously have cost Dr. Mumby much labour, but they will prove of the greatest value for purposes of comparison in the future. One of the results of the Portsmouth tables is to show, in the words of Dr. Mumby, "that while the conditions of life in Portsmouth are slightly inferior to those enjoyed by the inhabitants of Brighton, a little superior to those of Londoners, and remarkably similar to those enjoyed by the inhabitants of England and Wales as a whole, they are markedly superior to those under which the inhabitants of Manchester, Liverpool, and Glasgow spend their existence," and the tables furnished in the appendix illustrate these points.

Lowestoft Urban Sanitary District.—Mr. J. T. Thomas furnishes in his current annual report the following figures relative to the death-rates per 1000 from phthisis in some of the English health resorts:—

Eastbourne (four years' average)	1·05
Southport (five years' average)...	1 49
Brighton (five years' average)	1·54
Bournemouth (four years' average)...	3·27
Hastings (last year)	1 97
Scarborough (five years' average)	1 44
Lowestoft (six years' average)	0 92

These figures are of some interest, but clearly it would be useless to attempt to infer anything from them unless definite information were given both as to whether in all cases the deaths taken account of included those of visitors, and as to the number of visitors suffering from phthisis in each place. During 1896 Mr. Thomas closed certain schools owing to the prevalence of scarlet fever amongst the scholars, and he speaks highly of the good results of closure. Enteric fever and diphtheria are stated to be practically endemic in Lowestoft, and Mr. Thomas, as also does Dr. Copeman, who recently inspected the district, considers that the pollution of the subsoil caused by the privy middens is an important factor in the causation and perpetuation of this endemicity. In advising the conversion of privies into water closets Mr. Thomas points out that if the expense is considered to preclude the general adoption of proper water closets, "waste water closets" might under certain conditions be introduced, and he observes that it has been decided that no water-rates can be charged for such closets. Instances are recorded in the report before us of diphtheria having been introduced into lodging houses by children from London who had recently recovered from the disease, and in these cases the bacillus of diphtheria was discovered in the throats of the London children. The sewage disposal arrangements at Lowestoft appear to be far from satisfactory, and we read that the beach outlet of the main sewer has been a complete wreck during the year, its mouth having been buried in sand for some seventeen hours out of every twenty-four and having to be dug out every day. We are not surprised, under these circumstances, to hear that there have been complaints of foul smells from the street gullies.

Kingston-upon-Thames Urban Sanitary District.—In considering the health of school children Mr. Beale Collins suggests that if the seeing and hearing powers were tested in quite early childhood any defects discovered might, in many cases at least, be materially improved, if not entirely cured. He thinks that the cost in relation to the benefit would be in Kingston quite infinitesimal. The examination of the teeth of school children is also urged by Mr. Collins. There has recently been a heavy mortality from measles in Kingston, and Mr. Collins thinks that the notification of the first case of the disease in a house would afford very valuable information and enable a correct idea to be formed as to the desirability, in any given outbreak, of school closure. He thinks, too, that an effort might be made to isolate some of the cases, and he suggests that the foundation of a small hospital for measles would not be an unfitting memorial of the longest reign.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6562 births and 3585 deaths were registered during the week ending May 8th. The annual rate of mortality in these towns, which had been 18·8 and 18·3 per 1000 in the two preceding weeks, further declined last week to 17·0. In London the rate was 15·5 per 1000, while it averaged 18·1 in the thirty-two provincial towns. The lowest rates in these towns were 11 8 in Norwich, 12·0 in Cardiff, 12·5 in Croydon, and 12·6 in Derby; the highest rates were 25·6 in Manchester, 25·8 in Bolton, 25·9 in Salford, and 30·4 in Preston. The 3585 deaths included 315 which were referred to the principal zymotic diseases, against 367 and 351 the two preceding weeks; of these, 20 resulted from measles, 10 from scarlet fever, 26 from diphtheria, 35 from whooping-cough, 1 from enteric fever, and 15 from diarrhœa. No death from any of these diseases was recorded last week in Croydon, in Swansea, or in Halifax, while they caused the highest death-rates in Cardiff, Burnley, Manchester, and Salford. The greatest mortality from measles occurred in Cardiff, Bolton, Manchester, and Salford; and from whooping-cough in Burnley, Gateshead, Plymouth, Bristol, Oldham, and Manchester. The mortality from "fever" showed no marked excess in any of the large towns. The 43 deaths from diphtheria included 26 in London, and 4 in Birmingham. No fatal case of small-pox was registered during the week under notice either in London or in any other of the thirty-three large towns. There were 11 cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, the 8st inst., against 11, 7, and 12 at the end of the three preceding weeks; 3 new cases were admitted during the week, against 6 in the preceding week. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2385, against 2406, 2442, and 2380 on the three preceding Saturdays; 231 new cases were admitted during the week, against 216, 269, and 223 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 289 and 273 in the two preceding weeks, further declined to 232 last week, and were 110 below the corrected average. The causes of 51, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of

Hosted by Google

death were duly certified in Bristol, Cardiff, Leicester, Newcastle-upon-Tyne, and in ten other smaller towns; the largest proportions of uncertified deaths were registered Liverpool, Blackburn, Halifax, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·6 and 22·0 per 1000 in the two preceding weeks, further declined to 20·7 during the week ending May 8th, but exceeded by 3·7 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·1 in Leith and 15·0 in Dundee to 22·9 in Edinburgh and 23·3 in Glasgow. The 616 deaths in these towns included 34 which were referred to whooping-cough, 29 to measles, 18 to diarrhœa, 6 to diphtheria, and 6 to "fever" (principally enteric). In all, 93 deaths resulted from these principal zymotic diseases, against 102 and 127 in the two preceding weeks. These 93 deaths were equal to an annual rate of 3·1 per 1000, which was 1·6 per 1000 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had increased in the four preceding weeks from 38 to 45, declined again to 34 last week, and included 21 in Glasgow and 9 in Edinburgh. The deaths referred to measles, which had been 39 and 52 in the two preceding weeks, declined to 29 last week, of which 15 occurred in Glasgow and 12 in Edinburgh. The 6 fatal cases of diphtheria corresponded with the number in the preceding week, and included 5 in Glasgow. The deaths referred to "fever," which had been 4 and 6 in the two preceding weeks, were again 6 last week, of which 3 occurred in Glasgow and 2 in Dundee. The deaths from diseases of the respiratory organs in these towns, which had been 165 and 128 in the two preceding weeks, rose again to 134 last week, and exceeded by 46 the number in the corresponding period of last year. The causes of 46, or more than 7 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 34·6 and 29·5 per 1000 in the two preceding weeks, rose again to 33·7 during the week ending May 8th. During the past five weeks of the current quarter the death-rate in the city has averaged 32·4 per 1000, the rate during the same period being 16·8 in London and 27·0 in Edinburgh. The 226 deaths registered in Dublin during the week under notice showed an increase of 28 upon the number in the preceding week, and included 35 which were referred to the principal zymotic diseases, against 41 and 36 in the two preceding weeks; of these, 16 resulted from whooping-cough, 8 from measles, 4 from scarlet fever, 3 from "fever," 2 from diphtheria, and 2 from diarrhœa. These 35 deaths were equal to an annual rate of 5·2 per 1000, the zymotic death-rate during the same period being 1·3 in London and 4·5 in Edinburgh. The fatal cases of whooping-cough, which had been 14 and 13 in the two preceding weeks, rose again to 16 last week. The deaths referred to measles, which had been 19 and 16 in the two preceding weeks, further declined to 8 last week. The 4 fatal cases of scarlet fever exceeded the number registered in any recent week, while the mortality from diphtheria and from "fever" corresponded with that recorded in the preceding week. The 226 deaths in Dublin last week included 44 of infants under one year of age and 37 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons exceeded the numbers recorded in the preceding week. Six inquest cases and 2 deaths from violence were registered; and 75, or one-third, of the deaths occurred in public institutions. The causes of 16, or more than 7 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING APRIL, 1897.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during April in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 7·2 per 1000 of the population, estimated at 4,463,169 persons in the middle of this year. In the three preceding months the rates had been 9·0, 8·7, and 7·8 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Marylebone, Hampstead, St. Martin-in-the-Fields, City of London, St. George Southwark, and Lewisham; while they showed the largest excess in Bethnal Green, Whitechapel, Poplar, St. Olave Southwark, Battersea, and Greenwich. Eleven cases of small-pox were notified in London during April, against 8, 48, and 8 in the three preceding months; of these, 4 belonged to Poplar, 2 to the Port of London, and 1 each to Islington, Hackney, St. George-in-the-East, Battersea, and Camberwell sanitary areas. There were 12 small-pox patients under treatment in the Metropolitan Asylum Hospitals at the end of April, against 8, 43, and 17 at the end of the three preceding months; 8 new cases were admitted during the month, against 7, 53, and 8 in the three preceding months. The prevalence of scarlet fever in London showed a slight increase upon that recorded in the preceding month; this disease was proportionally most prevalent in Chelsea, Shoreditch, Whitechapel, St. George-in-the-East, Bermondsey, Battersea, and Greenwich sanitary areas. The Metropolitan Asylum Hospitals contained 2330 scarlet fever patients at the end of March, against 3246, 2775, and 2468 at the end of the three preceding months; the weekly admissions averaged 225, against 245, 228, and 208 in the three preceding months. The prevalence of diphtheria in London showed a slight further decline from that recorded in recent months; among the various sanitary areas this disease showed the highest proportional prevalence in Hackney, Clerkenwell, St. Luke, Bethnal Green, Whitechapel, Limehouse, Poplar, Greenwich, and Lee. There were 764 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of April, against 897, 855, and 776 at the end of the three preceding months; the weekly admissions averaged 127, against 101 in each of the two preceding months. The prevalence of enteric fever in London showed a further decline from that recorded in recent months; this disease was proportionally most prevalent in Hammersmith, Westminster, and Lee sanitary areas. Erysipelas showed the highest proportional fatality in St. Martin-in-the-Fields, Clerkenwell, Holborn, Bethnal Green, and Limehouse sanitary areas. The 21 cases of puerperal fever notified during April included 3 in Kensington, and 2 each in Hammersmith, Poplar, Lambeth, Battersea, and Greenwich sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, May 1st, the deaths of 5693 persons belonging to London were registered, equal to an annual rate of 16·6 per 1000, against 18·2, 18 5, and 17 4 in the three preceding months. The lowest death-rates during April in the various sanitary areas were 9·6 in Lee, 10·2 in St. George Hanover-square, 11·7 in Wandsworth, 12 4 in Lewisham (excluding Penge), 12·5 in Hampstead, and 12·8 in Rotherhithe; the highest rates were 22·5 in Limehouse 22·7 in St. Luke, 23·6 in St. Martin-in-the-Fields, 23 7 in City of London, 24·0 in St. George Southwark, 25·6 in St. George-in-the-East, and 29·8 in St Saviour Southwark. During the four weeks of April 511 deaths were referred to the principal zymotic diseases in London; of these, 186 resulted from whooping-cough, 130 from diphtheria, 85 from measles, 46 from diarrhœa, 41 from scarlet fever, 23 from enteric fever, and not one from small-pox. These 511 deaths were equal to an annual rate of 1·5 per 1000. The lowest zymotic death-rates last month were recorded in Kensington, St. George Hanover-square, St. James Westminster, Marylebone, Islington, Strand, and Rotherhithe; and the highest rates in Holborn, Bethnal Green, Whitechapel, Limehouse, St. George Southwark, and Bermondsey sanitary areas. The 85 fatal cases of measles were little more than a fourth of the corrected average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, and Greenwich sanitary areas. The 41 deaths referred to scarlet fever were 23 below the corrected average number; the mortality from this disease showed no marked excess in any of the sanitary areas. The 130 fatal cases of diphtheria exceeded by 4 the corrected average

* Including 21 cases of membranous croup.

† Including deaths from membranous croup.

Hosted by Google

number; among the various sanitary areas this disease showed the highest proportional fatality in Chelsea, Hackney, St. Luke, Whitechapel, Poplar, and Bermondsey. The 186 deaths from whooping-cough were 99 below the corrected average number; this disease was proportionally most fatal in Chelsea, St. Giles, Holborn, St. Luke, St. George Southwark, Bermondsey, and Lambeth sanitary areas. The 23 fatal cases of enteric fever were 8 below the corrected average number; this disease showed the highest proportional fatality in Stoke Newington sanitary area. The 46 deaths from diarrhœa were 9 below the corrected average number. In conclusion, it may be stated that the mortality in London during April from these principal zymotic diseases was more than 40 per cent. below the average.

Infant mortality in London, measured by the proportion of deaths under one year of age to registered births, was equal to 118 per 1000 during April, and was considerably below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. George Hanover-square, St. Martin-in-the-Fields, Rotherhithe, Wandsworth, Woolwich, Lee, and Plumstead; and the highest rates in St. James Westminster, Bethnal Green, St. George-in-the-East, St. Saviour Southwark, St. Olave Southwark, Bermondsey, and Lambeth.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN MOORES has been selected for appointment to the Scots Guards as an attached medical officer. Surgeon-Captain R. J. C. Cottell will shortly embark for South Africa. Surgeon-Major W. T. Johnston has proceeded from Devonport to Okehampton. Surgeon-Major H. L. Battersby and Surgeon-Captain H. E. Winter have been posted to the Station Hospital, Western Heights, Dover, for duty, Surgeon-Captain G. S. McLoughlin has been ordered to Cork for duty, and Surgeon-Major Hetherington has been posted to Dublin.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of the following officers of the Army Medical Staff are placed temporarily at the disposal of the Government of the North-Western Provinces and Oudh for employment on plague duty:—Surgeon-Captain C. Dalton, Surgeon-Captain J. F. M. Kelly, Surgeon-Captain E. H. Condon, and Surgeon-Lieutenant E. B. Steel. The services of the undermentioned officers of the Army Medical Staff are placed temporarily at the disposal of the Government of Bombay for employment on plague duty:—Surgeon-Major J. C. Culling and Surgeon-Captain J. E. Brogden.

NAVAL MEDICAL SERVICE.

The undermentioned Staff Surgeons have been promoted to the rank of Fleet Surgeons in Her Majesty's Fleet:—George Sprey Smith and Leonard Henry Kellett.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain William George Creswell resigns his commission.

VOLUNTEER CORPS.

Artillery: 2nd Glamorganshire: Surgeon-Lieutenant-Colonel C. T. Vachell resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the Corps on his retirement. 1st Monmouthshire: Surgeon-Lieutenant D. T. Richards to be Surgeon-Captain. *Rifle:* 4th Volunteer Battalion (the Manchester Regiment): David Livingston Hamilton, gent., to be Surgeon-Lieutenant. 1st Volunteer Battalion the Highland Light Infantry: George Roy Fortune, gent., to be Surgeon-Lieutenant.

CADET BATTALION.

1st Cadet Battalion the Buffs (East Kent Regiment): C. W. Scott is re-appointed Acting Surgeon.

DEATHS IN THE SERVICES.

Dr. Henry Vandyke Carter, Deputy Surgeon-General, I.M.S., and honorary surgeon to the Queen, died at his residence at Scarborough on May 4th.

THE HEALTH OF THE TROOPS IN INDIA.

In addition to the foregoing we find that our Anglo-Indian contemporary, the *Civil and Military Gazette*, contains a lengthy article under the heading of "A Social Problem in the Army," which has a direct bearing upon a subject that has occupied, and is still occupying, the attention of the Governments of India and this country. It is stated in the article in question that the space set apart for the recreation and reading-rooms for the troops quartered in India is, as a rule, miserably inadequate; and attention is called to the fact that there is an almost universal absence of any place outside the barracks to attract the men and enable them to meet their friends of other corps and spend a few hours in the evening, instead of going into the bazaars, with all their temptations and insanitary surroundings. Officers have their clubs where they can meet together, and the men require something of a similar kind, to be organised and managed by themselves. It is thought that rules might be easily framed for safeguarding such clubs against abuse and for securing social propriety of conduct. The soldier of the present day is far better educated and much more sensitive to the opinion of his comrades than was formerly the case. It is quite natural that he should desire to have some place of resort not under military management, and we have always thought that if something could be done in this direction it would be a very excellent thing. The Indian Government, now that it is considering how to limit the spread of a certain class of contagious disease, might give its attention to this subject. Military life in an Indian cantonment is very monotonous, and soldiers need some place to which they can resort and where they can amuse themselves in their own way.

INSPECTION OF FIELD SERVICE EQUIPMENT FOR INDIA.
